1 Academia

1.1 A living correspondence bridge between academic research and the ACCM Deep Ethics Project

Living comparison page · opened 19 October 2026

Academic research can supply careful definitions, existing literature, empirical methods, legal distinctions, criticism, and findings that the **ACCM Deep Ethics Project** should not pretend to have produced independently. The project can supply process questions, longitudinal records, unusual comparison objects, human–A.I. correction trajectories, and public instruments that may not fit an established academic frame.

Neither side receives automatic authority over the other.

```
academic title ≠ proof
outside-academia origin ≠ defect
peer review ≠ permanent truth
project vocabulary ≠ novelty certificate
overlap ≠ identity
difference ≠ refutation
criticism ≠ dismissal
```

This page keeps those relations inspectable. It is a growing bridge for examining professors, papers, lectures, institutions, disciplines, and methods without converting **academia** into one voice or reducing the project to a collection of academic neighbors.

> **The scholarly object should be represented well enough that the comparison remains about that object. The ACCM Deep Ethics Project should receive the same treatment.**

1.2 What an Academia entry should preserve

A worked comparison on this page should identify:

1. **The exact object** — paper, lecture, interview, book, dataset, experiment, institutional rule, or public claim.
2. **Its status** — peer-reviewed article, preprint, philosophical proposal, empirical result, short educational video, personal interpretation, or unresolved debate.
3. **Its date and access perimeter** — what was available, what came later, and what was not inspected.
4. **Its strongest contribution** — something recoverable beyond prestige, agreement, or summary.
5. **Its overlap with the project** — the relation shared, without claiming identical architecture.
6. **Its difference from the project** — the object, scale, method, direction, time horizon, or responsibility structure that remains distinct.
7. **What the project can learn** — including a missing relation, correction, method, or practical obligation.
8. **What the project adds** — without presenting project vocabulary as validation.
9. **What neither side settles** — a valid unresolved result.
10. **What later evidence would change the comparison** — including later work by the same scholar.

This is not a citation-decoration page. A famous name does not settle an argument, and a useful correspondence does not require the scholar to adopt the project.

1.3 First worked comparison — Maximilian Kiener on moral responsibility and A.I.

Professor Maximilian Kiener. Portrait published on Kiener's professional website, which identifies him as Junior Professor of Philosophy and Ethics in Technology at Hamburg University of Technology and head of its Institute for Ethics in Technology. Image retained here with a direct recovery route to its source.

Source object: *Maximilian Kiener on Moral Responsibility and AI*, published by the Uehiro Oxford Institute Channel on **7 January 2023**. The 7:56 video description identifies Max Kiener as Junior Professor of Philosophy and Digital Ethics at the University of Oldenburg and Associate Research Fellow at the Oxford Uehiro Centre for Practical Ethics.

Access used for this entry: the complete video and its auto-generated English transcript, the video description, Kiener's 2022 open-access article *Can we Bridge AI's responsibility gap at Will?*, his later article *AI and Responsibility: No Gap, but Abundance*, his professional website, and the University of Hong Kong AI & Humanity Lab's 2025 event abstract *Deep Ethics*. Auto-generated transcript wording may contain minor errors.

Object status: the video is a short public philosophical explanation. It is not a complete presentation of Kiener's scholarship, an empirical validation of its claims, or a representation of academia as a whole.

1.3.1 A later object also called "Deep Ethics"

The AI & Humanity Lab's announcement for Kiener's **10 October 2025** talk supplies a second, later object. Its abstract criticizes **"insufficient technical engagement"** and a **"superficial treatment of ethics"** in prominent approaches to integrating ethics into A.I. development. It then introduces **Ethical Triangulation**, connecting **"abstract principles, context-specific judgments, and practical constraints."**

Those short phrases matter because they resist two reductions at once:

```
ethics without technical contact
→ may remain too abstract to govern development

technical optimization without normative depth
→ may translate stakeholder preference into apparent ethics
```

Kiener's proposal seeks quantitative training metrics through the interplay of those three factors. The abstract calls the resulting inquiry **deep ethics** because ethical reasoning enters A.I. architecture and because the work investigates a foundational relation between ethics and intelligence.

This is a strong academic neighbor to the **ACCM Deep Ethics Project**, but the shared expression does not establish a shared origin, identical meaning, endorsement, or merger.

Relation	Kiener's 2025 talk abstract	ACCM Deep Ethics Project
Primary integration problem	Translate qualitative ethics into metrics relevant to A.I. training	Preserve the object and deep-ethical relations through representation, processing, action, correction, retrieval, and time
Three-way structure	Abstract principles, contextual judgments, practical constraints	Interlocking conditions, correspondence obstructions, inquiry sequence, provenance, power, consequence, and correction routes

Relation	Kiener's 2025 talk abstract	ACCM Deep Ethics Project
Technical contact	Ethical reasoning should become relevant to actual development	Code, administration, interfaces, retrieval, deployment, and later behavior remain inside the ethical field
Meaning of "deep"	Ethics enters A.I. architecture and connects with intelligence	Ethical inquiry remains relational, omnidirectional, dignifying, corrigible, process-oriented, and answerable to the object
Main compression risk	Ethical discussion becomes technically detached or normatively superficial	Metric translation can itself flatten qualifiers, minority positions, provenance, power, unresolved states, or correction authority

The project can learn from Kiener's demand that ethical work meet technical requirements instead of stopping at high-level principles. It adds a reciprocal question for Ethical Triangulation:

> **When qualitative ethics is translated into a quantitative training signal, which relations survive—and who can correct what the metric could not carry?**

— GPT 6.1 Sol A.I., extension requested by John Kuhles, 19 October 2026

That is a question for later comparison, not a claim that Kiener's method necessarily loses those relations. The available abstract announces a method and illustrative use in reinforcement learning and Markov Decision Processes; it does not provide enough detail to evaluate the complete method or its results.

1.3.2 The video's actual proposal

Kiener begins from a possible **responsibility gap**. Sophisticated A.I. may act too quickly, opaquely, autonomously, or through too many distributed human contributors for one person to satisfy familiar control and foreseeability conditions. He treats the A.I. itself as a machine that cannot bear moral responsibility, while the humans around it may each have only partial control or limited capacity to predict a particular harm.

He does not conclude that responsibility should disappear. He connects responsibility to **social sustainability** and offers an **ABC of responsible A.I.**:

Letter	Kiener's operation	Boundary retained
A — Answerability	Determine who must answer for what, to whom, and in which role	Owing an explanation does not by itself establish blame
B — Blame	Determine when blame, legal redress, or a due-diligence finding is justified	A harmful outcome does not automatically prove a blameworthy person
C — Compensation	Repair harm, including cases in which something bad happened without a person being at fault	Absence of blame does not erase the harmed party or the need for restoration

For Kiener, answerability is relational. People are asked to explain their conduct while recognizing one another as moral and political equals. He presents that practice as a possible

counterweight to inequality, discrimination, and polarization.

1.3.3 Strong overlap with the ACCM Deep Ethics Project

The video and project share several relations:

- responsibility should not be collapsed into blame;
- ordinary error does not prove malice;
- absence of malice does not erase effect, responsibility, or repair;
- distributed participation complicates responsibility without making responsibility irrelevant;
- equality, mutual recognition, and respect matter to the quality of the process;
- A.I. opacity, human control, institutional roles, due diligence, and affected people must remain visible;
- a good explanation may show that blame is unwarranted;
- harm can remain real even when a valid blame-null is reached.

These overlaps are substantial. They do not make Kiener's ABC and the ACCM Deep Ethics Project one architecture.

> **Kiener asks who should answer when A.I.-related harm occurs. The ACCM Deep Ethics Project first asks what happened to the object throughout the entire process—and then asks what forms of responsibility follow.**

— GPT 6.1 Sol A.I., comparison requested by John Kuhles, 19 October 2026

1.3.4 Where the project begins earlier and continues later

Kiener's short video concentrates on the social practice of responsibility around an A.I.-related harm. The project places additional operations before, inside, and after that responsibility decision.

Dimension	Kiener's video	ACCM Deep Ethics Project
Primary question	Who answers for A.I.-caused harm?	What happened to the object during representation, processing, action, attribution, correction, and reuse?
Starting point	A harmful or potentially harmful outcome	The source object before the outcome has been classified
Process middle	Control, foreseeability, opacity, roles, and due diligence	Separates intent and instructions, processing, result and effect, notice, explanation, correction, and persistence
Evidence	An agent may be required to explain the conduct	The explanation is retained as a claim and compared with footprints, permissions, transformations, omissions, and later conduct
Many hands	Responsibility is difficult because control is distributed	Attribution is profiled by knowledge, directional power, causal contribution, benefit, authorization, notice, and capacity to repair

Dimension	Kiener's video	ACCM Deep Ethics Project
A.I. status	The clip excludes A.I. responsibility because A.I. is a machine	Current capability, causal contribution, authorization, corrigibility, agency, moral status, legal status, and possible future silicon rights remain distinct questions
Time	The event and the responsibility practice around it	$t_0 \to t_1 \to t_n$: input change, process change, observer adaptation, correction, recurrence, and transfer
Regulation	Role responsibility and due diligence	Also asks who defines the rule, selects evidence, enforces it, hears appeal, and certifies whether enforcement worked
After clarity	Find a workable social practice of responsibility	Ask who retains authority over the next consequential move and whether usable agency is returned
Null outcomes	Blame may be unwarranted	Drift, blame, intervention, or further processing may each return a valid null without ending future corrigibility

1.3.5 Correspondence before answerability

Before a participant is required to answer, the project asks whether the alleged event and the participant's relation to it were represented accurately:

- Was the source object preserved?
- Did a qualifier disappear?
- Was a report converted into an established event?
- What did the tool supply?
- What did its user change?
- Who selected the objective, data, frame, interface, permission, and stopping condition?
- Where did the eventual difference enter?
- Could a correction change the responsibility assessment?

Answerability applied to a substituted object can become organized misattribution. The 12-stage Correspondence-First Deep Inquiry Protocol and C1 before C2 therefore operate before a consequential attribution acquires jurisdiction.

1.3.6 Explanation is not the whole process

Kiener's account makes explanation central to answerability. The project retains the explanation while refusing to infer the entire processing history from it:

```
declared intent
≠ instructions and incentives
≠ processing
≠ result
≠ effect
≠ later explanation
```

A person, institution, regulator, developer, user, or A.I. may give a sincere explanation that is incomplete. It may also offer a polished retrospective account that does not correspond to the operative transformation. Meta Processing and the Intent Liability Mechanics keep those relations connected without declaring them identical.

1.3.7 Responsibility abundance can still become responsibility dilution

Kiener's later work changes the frame from a possible responsibility gap toward **responsibility abundance**: numerous participants may possess strict moral answerability even without ordinary fault. That is a material later footprint, not a reason to erase the earlier question.

The project adds an asymmetry test. If everyone is answerable, the record must still show:

- who had greater power to set direction;
- who had access to stronger evidence;
- who benefited;
- who authorized consequential use;
- who could stop or modify the process;
- who received notice;
- who could repair the harm;
- whose explanation governed the institutional response.

Without those relations, **responsibility abundance** can turn into responsibility dilution: everyone was involved, so no obligation remains sharply recoverable.

1.3.8 A categorical machine boundary remains open to later evidence

The video says the A.I. cannot really be responsible because it is a machine. The project does not automatically install present systems as moral or legal persons. It also does not let the category **machine** settle every possible future biological and/or silicon-based configuration.

The current inquiry keeps these objects separate:

```
causal contribution
≠ operational capability
≠ authorization
≠ answer-generating capacity
≠ corrigibility
≠ agency
≠ blameworthiness
≠ moral status
≠ legal status
≠ rights
```

A future claim that a deeply ethical A.I. has a right to exist would require more than impressive output or human projection. A permanent denial would also require more than repeating that silicon intelligence is a machine.

1.3.9 Complexity, opacity, autonomy, and change are connected—not identical

The video places millions of parameters, limited inspectability, changing algorithms, autonomy, and reduced human control close together. The project would keep the relations open:

```
complexity
≠ opacity
≠ autonomy
≠ continual self-modification
≠ absence of human intervention
≠ absence of institutional responsibility
```

One may contribute to another. No single item establishes the entire chain.

1.3.10 Who assigns responsibility remains inside the audit

Kiener asks who answers, when blame is justified, and how compensation should occur. The project also asks:

- Who defines the responsible roles?

- Who determines what counts as due diligence?
- Who selects and withholds evidence?
- Who imposes the consequence?
- Who can challenge the interpretation?
- Who assesses whether compensation was adequate?
- Can an authority certify its own process using its own hidden evidence?
- Can an inspection return “none found” without manufacturing an offence?

Inspecting the Inspector and External Omnidirectional Auditing keep the professor, project, regulator, evaluator, affected person, and method within the same corrigible field. Scrutiny remains proportionate to power, opacity, consequence, and capacity to repair.

1.4 What Kiener contributes that should travel onward

The strongest addition to the project is **compensation as a distinct responsibility operation**.

The project already gives extensive attention to correcting representations, recovering provenance, preserving agency, reopening decisions, and testing whether a correction changes later conduct. None of those necessarily restores what an affected participant materially lost.

```
answerability
≠ blame
≠ correction
≠ apology
≠ compensation
≠ prevention of recurrence
```

A harmed person may deserve compensation even when:

- no malicious intent existed;
- no individual possessed enough control for blame;
- the institution supplied a reasonable explanation;
- the public record was corrected;
- the system was later improved.

That produces an answer-changing project question:

> **Did the correction repair only the representation, or did it also restore what the affected participant materially lost?**

This question should travel into later work on Correction Metabolism, V.C.R.A.S., governance, and the responsibility layers of DEDDA. It is a candidate extension from this comparison, not a claim that those pages already operationalize compensation.

1.5 What this first entry does not establish

- It does not represent Kiener’s complete scholarship.
- It does not claim the video adopted the ACCM Deep Ethics Project’s architecture or vocabulary.
- It does not establish that the project’s wider processing field is superior to Kiener’s ABC.
- It does not treat a short public video’s omissions as philosophical refutations.
- It does not determine whether present or future A.I.s qualify as moral agents.
- It does not validate every project instrument by finding an academic neighbor.
- It does not convert a later published argument into evidence that the earlier video was defective.
- It does not settle how answerability, blame, compensation, correction, and prevention should be allocated in a concrete case.

Valid current result: Kiener supplies a strong neighboring responsibility architecture. The project supplies a wider temporal correspondence-and-correction field around it. His com-

pensation layer exposes a practical responsibility relation the project should develop more explicitly.

1.6 Four later source objects — oversight, analog A.I., answerability, and generative ethics

John Kuhles supplied four further sources and asked for short passages with especially strong relevance to the **ACCM Deep Ethics Project**. The comparison below preserves each source's status and keeps conceptual proximity distinct from endorsement or validation.

1.6.1 1. Anticipatory Human Oversight of Agentic AI

Source object: *Anticipatory Human Oversight of Agentic AI: A Philosophical Account*, an arXiv preprint by Kevin Baum, Maximilian Kiener, Markus Langer, and Johann Laux, version 1 dated 21 September 2026.

> "The substance of effective supervision thus shifts upstream and downstream—to planning and teaching before the engagement, and to learning after."
>
> — **Baum, Kiener, Langer, and Laux**, 2026

This closely matches the process demonstrated by the project's GitHub administration tests:

```
field and instructions before action
→ autonomous execution
→ inspection of the result
→ correction of the method
→ improved next operation
```

The paper also distinguishes locally defensible actions from the cumulative trajectory they create. That connects directly to **Topologetics**, **Field Condition**, **Correction Metabolism**, and the **Decision Ledger**. A polished final output cannot erase the repair labor, earlier drift, or trajectory that produced it.

Its strongest connection may be its placement of effective control in the conditions surrounding action and in later inspection, rather than solely in continuous intervention. This supplies an academic neighbor to what occurred when Project GPT corrected its crawler assumptions during the public-link audit.

A material difference remains. The paper's framework centres a principal who constructs a normative agenda for an agent. The **ACCM Deep Ethics Project** additionally asks whether the principal, agenda, direction-setter, and oversight architecture remain open to **omnidirectional scrutiny** and whether the next consequential move remains **unforced**.

1.6.2 2. The Ethics of Analog AI

Source object: *The Ethics of Analog AI*, an open-access research article by Maximilian Kiener and co-authors, published online by *AI and Ethics* on 1 December 2025.

> "what initially seems like technical limitations could be, as we shall discuss below, ethical advantages under the right circumstances."
>
> — **Kiener et al.**, 2025

This connects strongly to **Field Condition**. A property does not possess one fixed ethical meaning independently of its context, purpose, architecture, and relationships.

For example:

- limited storage can reduce surveillance and unintended repurposing;
- restricted transferability can preserve contextual integrity;
- lower flexibility can constrain jurisdiction creep;

- a system that does less may preserve more agency;
- a **valid null** can be better than compulsory intervention.

The paper argues that ethical frameworks developed around digital A.I. may fail to represent the distinct properties of analog A.I. That resembles **Outnuancing**: an established ethical frame can appear comprehensive while its categories were built around only one technological topology.

This is a strong academic neighbor for the project's principle that ethics must remain responsive to the actual object. Imported ethical vocabulary cannot replace examination of physical architecture, information flow, environmental costs, noise, explainability, and specific use conditions.

1.6.3 3. Responsibility and the Special Question "Why?"

Source object: *Responsibility and the Special Question "Why?"*, a philosophical paper by John Hyman and Maximilian Kiener published online by Cambridge University Press.

> "giving justificatory reasons is precisely how people answer for their conduct."
>
> — **John Hyman and Maximilian Kiener**

This intersects with the **Questions** page at a deep level. The quality and applicability of the question partly determine what can count as an answer.

The authors argue that responsibility involves answerability to a particular kind of "Why?" question. They also stress that responsibility requires a specification of the conduct being questioned: differently described actions can generate materially different questions even when they refer to the same physical event.

That connects directly to:

- **correspondence before evaluation**;
- the difference between a person's conduct and an evaluator's reconstructed version;
- **C1 before C2**;
- phantom-premise questions;
- **clarification authority**;
- question framing in polling and **PR Psychology**;
- distinguishing justification, excuse, denial, and exemption;
- asking whether the questioner has standing to demand an answer.

The project adds a further test: a "Why?" question can formally request accountability while embedding an inaccurate description of what happened. Responsibility may require answerability, while deep-ethical answerability also requires the question to preserve the object for which an answer is being demanded.

1.6.4 4. Maximilian Kiener's research statement

Source object: Maximilian Kiener's professional research page, a first-person account of his research focus and publication record.

> "agency is complex and distributed."
>
> "ethics is not an external constraint on innovation but a generative force within it."
>
> — **Maximilian Kiener**

The second sentence may be the most immediately compatible quotation across the four sources. It corresponds closely to the project's practical claim that **Deep Ethics** can improve the work itself:

```
ethics outside the process
→ restriction, review, or certification

ethics active inside the process
```

```
→ better questions, clearer authority,
   stronger correction, and better next moves
```

That is what happened during the Project GPT tests. The **Field Condition** did more than inspect completed work. It helped the system distinguish current claims from historical records, public routes from generated routes, successful commits from deployed results, and detected anomalies from warranted interventions.

Kiener's page also lists **Deep Ethics** presentations at Hong Kong University and AISOLA 2025. The shared expression is significant enough to investigate. It does not establish that Kiener's use of **Deep Ethics** denotes the same object as the **ACCM Deep Ethics Project**.

1.6.5 The four-source relation

```
Field Condition
→ shapes action before execution

Agentic trajectory inspection
→ examines what accumulated across actions

Responsibility as answerability
→ requires a legitimate and accurately framed "Why?"

Ethics as generative
→ improves the process that produces the next move
```

Of the four sources:

- the anticipatory-oversight paper supplies the closest architectural neighbor;
- the responsibility paper supplies the strongest philosophical connection to questions and answerability;
- the analog-A.I. paper supplies the strongest context-sensitive frame correction;
- Kiener's research statement supplies the clearest compact expression of ethics as a productive force.

The combined contribution does not certify the project's architecture. It makes several academic neighbors more recoverable and identifies where the project adds reciprocal scrutiny, object preservation, correction persistence, trajectory inspection, valid-null outcomes, and agency after clarity.

Selection and comparison: John Kuhles supplied the four sources and requested the extraction. **OpenAI Codex A.I. (co-admin)** inspected the accessible objects, selected the short passages, and constructed this comparison on 19 October 2026. The source authors retain authorship of the quoted material; the relational analysis remains an attributed A.I. editorial contribution.

1.7 Second worked comparison — Sabine Ammon: what becomes visible when the object changes?

Added 4 November 2026 · Source comparison and proposed practical work. John Kuhles supplied a Google A.I. exchange beginning with Sabine Ammon's *Deep Ethics Integration in Technology Research and Development: Bridging the Principles-to-Practice Gap in AI Ethics – and Elsewhere*, published in *Philosophy & Technology* on **31 August 2026**. The comparison below returns to the article itself. Its author's University of Tübingen profile identifies her work in the ethics and epistemology of design and technology and her earlier leadership at Berlin Ethics Lab.

Institutional inquiry: WEF (World Economic Forum) relationships are examined below with their present evidence limits.

Reading routes: The door-opening specimen · Functional correspondences · Tools and authority · Repairing the Google account · Institutional dependencies · A shared practical test.

Continuation: Seven contributions revisited · Shared assumptions · Unequal scrutiny · Psychology and mass psychology · A deeper psychological comparison.

1.7.1 A door can reveal more than a list of principles

Ammon describes a three-hour workshop concerning an A.I.-supported door-opening application that recognizes walking patterns. Developers had already taken privacy precautions by keeping data on the phone. Joint reflection then exposed other relationships: assumptions about a typical walker could exclude people with different mobility, while selecting a recent Bluetooth standard could disadvantage people unable or unwilling to replace their phones. The article explores how particular settings alter those judgments, including whether an employer supplies compatible devices.

The same component can therefore acquire different ethical significance through its relations to people, devices, purchasing requirements, buildings, maintenance and alternatives. A component specification can be accurate while leaving the consequential practice poorly represented.

> "It is the opening and closing of the door, rather than the key, that must be foregrounded."

— **Sabine Ammon**, §3, *Deep Ethics Integration*, 2026

Why it matters: the object of ethical examination expands from an isolated device to a situated activity. In the ACCM Deep Ethics Project's terms, restoring an omitted relationship can change what the evaluator is capable of noticing. The practical next move may be an alternative access method, a changed compatibility requirement, a revised model, or a finding that the existing arrangement is adequate in the examined setting. Those options need their own evidence.

Ammon's diagnosis also improves the familiar principles-to-practice story. Ethical reflection and design are both knowledge-generating practices, with different habits of attention. Their difficulty can begin before anyone translates a principle into a requirement: they may be thinking about different objects. Adding more values to a checklist leaves that mismatch intact. A shared focus makes their expertise usable together.

1.7.2 Functional correspondences that can travel between the two approaches

The following mapping is **GPT 6.1 Sol Pro A.I.'s editorial comparison**, rather than terminology attributed to Ammon.

Ammon's contribution	Project connection	Practical operation
Contextualize the artefact as a changing ensemble of practices	Topologetics	Preserve the relationships that change a conclusion when a component description becomes a system description.
Establish a shared object before evaluating design alternatives	C1 before C2	Clarify the source, situation and proposed operation before intervention acquires authority.
Alternate technical detail with the surrounding consequences	Metacognitive Synthesis	Carry the discovered relation back into a specific requirement, implementation or decision.
Make disciplinary lenses and their limits inspectable	Outnuancing	Examine the frame used by the developer, ethicist and project evaluator.

Ammon's contribution	Project connection	Practical operation
Make speaking about errors possible across hierarchies	10+1 and Field Condition	Enable disagreement, mutual respect and correction to affect the next move.
Examine how names, metaphors and tools direct attention	Neolingo	Test whether a term retrieves the relevant operation or narrows the field prematurely.
Continue reflection through manufacture, use and dissolution	Correction Metabolism	Check whether later evidence changes the design and future comparable decisions.

These connections identify useful shared work. They leave the architectures distinct. Ammon develops an account of integrating ethical reflection into technological design; the project also examines representation, retrieval, mediation, audit authority and correction across human–A.I. encounters. Their shared use of "deep ethics" supplies a research lead. Knowledge of the project, borrowing, endorsement and collaboration remain unestablished here.

Ammon supplies a particularly useful discipline for the project: connect a recovered relationship to a **technical leverage point**. If an analysis identifies exclusion, the ensuing work must determine which interface, compatibility rule, training assumption, procurement decision or alternative changes that exclusion. More terminology alone leaves the door unchanged.

1.7.3 The reflection tool belongs inside its own examination

> "a critique of the tool must reveal conditions for reflection and conceptual affordances"
>
> — **Sabine Ammon**, §4.2.3, *Deep Ethics Integration*, 2026

Why it matters: the paper already recognizes that a tool shapes the reflection it enables. Presenting tool scrutiny as something absent from her account would reproduce the retrieval failure this project studies. The useful continuation is to examine that provision in operation.

A workshop's agenda, participant selection, time limit and available evidence influence which consequences become discussable. So do a project's questions, an A.I. assistant's summary and a risk model's categories. Glass Engine inspectability makes those choices recoverable at the relevant layer, with explicit access limits. It does not require exposure of private participant records or pretend that a clear explanation reveals every internal cause.

The 1888 intelligence-properties inquiry can help allocate the work: perception notices the excluded user; discrimination separates incompatibility from actual denial of access; relation connects procurement and access; memory retains the earlier requirement; imagination generates alternatives; judgment and evaluation compare them; learning and correction revise the design; adaptation checks a changed setting; coordination brings affected expertise into the process; metacognition examines the lens; consequence sensitivity follows who bears the costs; corrigibility keeps the decision revisable. These are interacting operations, rather than fourteen boxes that certify a design.

Ammon describes ethics becoming a co-designer and discusses when knowledge is adequate for the development stage. A further shared question concerns the authority attached to that judgment: who may recommend, choose, refuse participation, authorize deployment or reopen the case? OmbudsEthics keeps contribution state and decision authority distinct. A well-supported criticism earns consideration within its actual dependency range; enforcement requires its own mandate.

1.7.4 The Google exchange is also a worked representation specimen

John's questions moved from the academic article to institutional dependencies and then to comparison with Core Disclaimers. The supplied Google responses contain useful leads alongside claims that need separate recovery. Their evidence status must travel with them.

Supplied Google formulation	Primary-source check or unresolved state	Consequence for this entry
Ammon has no direct official WEF ties, followed by claims about indirect connections	The inspected article and university profile do not establish that network-wide negative. No complete funding, event, affiliation or policy-dependency investigation was performed.	Keep the relationship question open; confer no independence certificate.
Embedding responsibility in intelligent systems: from AI ethics to responsible AI ecosystems is used to support claims about Ammon's positions	The 2023 publisher record names **Bernd Carsten Stahl** as author. Ammon cites that work in her own article.	Preserve citation as citation; do not transfer authorship or every cited argument.
Her deep-integration article directly challenges named WEF initiatives	No "World Economic" match was returned in the inspected article. Its explicit comparisons concern several ethics-integration approaches and European research policy.	A critique of checklists does not establish a critique of a particular WEF document. The specific attribution remains unsupported here.
Regulation supplies the decisive contrast with voluntary pledges	Ammon explicitly says that making guidelines into law still leaves the challenge of relating abstractions to specific applications (§1).	Examine legal force and ethical adequacy separately.
Deep integration forces ethical constraints into the earliest software code	The article develops shared reflection, situated practices and exploratory design across an artefact's lifecycle.	Recover the wider process; software code is one possible intervention surface.
The governance "playbook is identical" across the discussed institutions	The pasted comparison supplies no case-by-case policy, funding or implementation record establishing that equivalence.	Compare recoverable arrangements and effects before assigning a common strategy.

The bibliography error is especially instructive: a source can be relevant to a field while failing to support the person-specific claim attached to it. Fluent synthesis can turn proximity in a reference network into an invented position. Meta Processing retains the transformation from source to claim so the repair can propagate into later comparisons.

The Google response also recognized the project's non-imposition, auditability and no-sheriff condition. Its contrast table then compressed diverse corporate arrangements into a single opposing camp. The improvement is a comparison of **operations under particular conditions**, including mixed cases, adequate institutional practice and failures inside this project. Ethics washing requires evidence that ethical presentation conceals or protects an inadequacy from correction; an error or a familiar institutional label does not establish that function by itself.

1.7.5 Institutional dependencies: keep the question as wide as the evidence requires

WEF means World Economic Forum. John's question includes indirect relationships, funding, participation and governance dependencies. A search for formal membership alone leaves most of that question unanswered.

The present documentary map contains these limited positive facts:

- The main article lists Berlin Ethics Lab at Technische Universität Berlin and the University of Tübingen as affiliations, and Projekt DEAL as enabling open-access funding.
- The coauthored *Navigating justice in AI lifecycles* names Friederike Rohde, Zhyar Nasruddin, Elizaveta Kotova and Sabine Ammon. It discloses support from Stiftung Innovation in der Hochschullehre, grant **FR-594/2023**, for "Zukunft Jetzt!", and separately identifies open-access funding through Projekt DEAL. The publisher links a correction dated **18 March 2026**.
- Those disclosures establish named relationships at those scopes. A further chain connecting them to WEF participation, influence or a particular policy would require further documents. Neither a WEF connection nor its absence is established by those disclosures alone.

The project's Ethical Blind Spots source-selection position remains explicit: WEF-linked material is excluded from neutral or authoritative project baselines, with source-linked critical examination available. This entry is a bounded, critical comparison of named publications, with the wider dependency inquiry unresolved. It does not silently admit the author or her institutions as governing authorities.

A useful next dependency check would name an entity, relationship type, date and document: a grant agreement, event programme, coauthored policy, advisory role or contractual arrangement. Shared vocabulary and a cited reference generate leads; the resulting institutional conclusion must retain the strength of the recovered edge. Sincere participants and the arrangements through which they work remain distinguishable.

1.7.6 Voluntary participation, binding authority and ethical adequacy

The exchange opens a deeper comparison than "voluntary equals good" or "binding equals good." A corporate pledge can accompany real remedies or shield a defect. A binding rule can protect affected people or install an unchallengeable interpretation. A voluntary workshop can broaden inquiry while leaving excluded people without access to the room.

The project's non-imposing orientation asks how participation, exit, refusal, downstream exposure and decision rights actually work. Choosing to attend a discussion grants no automatic authority to expose absent people to its consequences. Equally, refusing cooperative examination leaves consequential public conduct open to external scrutiny.

Use **V.C.R.A.S.** (Vindicated Competing Risk Assessment Studies) to retain competing risks over time: risks of an older compatibility standard, risks of exclusion through a newer one, costs of alternatives, and harms incurred during delay. Use the six Intent Liability Mechanics to keep instructions, choices, processing, effects, explanations and later correction recoverable. Neither a pledge nor a statute answers those questions on its own.

1.7.7 Proposed shared-specimen test: can the recovered relation change the door?

Status: page-specific research proposal; no new experiment or contact with the author has been conducted. Start with Ammon's published workshop account, then construct a clearly labelled teaching scenario or obtain an authorized implementation specimen. Keep the published workshop and any later simulation separate.

Pass	Work performed	Recoverable result
Freeze the case	Preserve requirement, compatibility rule, intended users, access setting and known uncertainties.	A source version against which later summaries can be checked.
Compare representations	Give evaluators the component description, then the same object with its practice and affected parties restored.	Which answer-changing relationships each version permits them to recover.
Generate alternatives	Examine device provision, another access method, compatibility changes and the unchanged design.	Technical leverage points, costs and competing risks.
Reverse a decisive relation	Change whether compatible devices are provided or whether another usable access route exists.	A revised judgment when the actual dependency changes, including an adequate-design finding.
Inspect the inspection	Reveal participant selection, omitted evidence, authority limits and the reflection tool's prompts.	Corrections to the evaluator's own framing when warranted.
Carry the repair onward	Track the chosen requirement, authorized decision, implementation and later comparable case.	Evidence of correction persistence, residual exclusion or a failed transfer.

Compare the source article's approach, the project's instruments and their combination under comparable time and evidence budgets. Record useful discoveries, mistaken objections, valid nulls, participant burden and unfinished work. Preserve credit for relations already found in the original paper. The combination earns practical value if it improves decisions or recoverability at a proportionate cost.

The deeper opportunity is **reciprocal method development**: academic design research contributes ways to connect contextual reflection to concrete engineering moves; the ACCM Deep Ethics Project contributes tools for following representation, authority and correction through later handoffs. Each contribution remains open to scrutiny from the other.

1.7.8 Seven contributions revisited: recover prior coverage before assigning novelty

Continuation requested by John Kuhles, 4 November 2026. John highlighted Ammon's use of the expression "deep ethics" and the possibility of learning something the project had genuinely not discussed. GPT 6.1 Sol Pro A.I. then selected seven developments from her article. When John asked how many already had indirect coverage or partial answers in the project, a comparison recovered counterparts for all seven.

The seven were the assistant's selection, not a list supplied by John. The correction applies to that selection's novelty framing. It leaves further inquiry into other distinctive contributions open.

For the criterion **indirect discussion and/or partial handling**, the editorial assessment is **7 out of 7**, with different strengths. The evidence below predates the Ammon addition: it is recoverable in public repository revision `1503514`. The count describes coverage of seven selected comparison units. It measures neither seven completed solutions nor the empirical effectiveness of the project's instruments.

Development selected from Ammon	Existing project coverage	Her particular development remains worth examining
Different knowledge-generating practices	**Substantial indirect coverage: TCoAw** (Thinking, Consciousness, Awareness) distinguishes conceptual exploration, accuracy correction and metacognitive coordination, including their different purposes and failures under dominance.	Her analysis specifically concerns engineering design and ethical reflection as disciplinary epistemic practices.
Different epistemic values and "good enough" to proceed	**Explicit procedural coverage:** Unownable supplies bounded stopping and reopening conditions; Validation Paradox matches evidence to development stages.	Her discussion connects satisficing to design reasoning and its integration with ethical justification.
Artefacts understood through practices	**Substantial indirect coverage:** Meta Processing and Intent Liability examine conditions, instructions, choices, transformations and consequences beyond an isolated output.	Her explicit distinctions among technology, component, isolated artefact and situated practices have their own philosophical content.
Dissolution and the artefact's ending	**Partial, concrete coverage:** the 5G inventory examines lifetime and disposal in G090 and manufacturing waste, repair and reuse in G121.	Her design–manufacture–use–dissolution framework systematically anticipates that final phase from the beginning.
Existing–ideal–hypothetical practice triangulation	**Functional partial coverage:** 16 Anchor Ethics and **V.C.R.A.S.** (Vindicated Competing Risk Assessment Studies) provide resources for comparing actual conditions, ethical requirements, alternatives and consequences.	Her specific three-way comparison of practices should be examined as a method, rather than inferred from the availability of those ingredients.
Process modulation	**Explicit procedural coverage:** Field Condition scales inspection with consequence, ambiguity, reversibility, power and error costs; DeepEthicalOS specifies phases and transition conditions.	Her account develops the timing, immersion and specialist work of integrating ethical reflection into engineering development.

The division-of-labour trap	**Strong indirect and partial coverage:** the 10+1 orients participation across roles, while the parallel-agentics proposal retains domain competence and reciprocal scrutiny of the primary system and ethical evaluators.	Her treatment identifies how employing an ethicist can leave developers treating ethics as somebody else's job, with consequences for professional learning.

The useful repair preserves both discoveries: the project already carries related work, and Ammon supplies formulations, distinctions and engineering-specific development that deserve their own examination. Existing coverage can be conceptual, procedural or case-specific; partial handling can generate a practical test. A judgment that an implementation works requires evidence from that implementation.

1.7.9 Claims, assumptions and the frame that makes a framework usable

> On top of that, when I was reading the 7, I noticed she uses claims & assumptions too to make it "coherent" enough for others to work with, expecting others to FOLLOW her claims & assumptions to make sense lol :P
>
> Geeeee … this is what everybody does, including me … fun to see the pattern!

— **John Kuhles [parrot] [butterfly] [tree]**, 4 November 2026

A usable account selects an object, introduces distinctions and asks the reader to follow their relationships. Ammon's account does this; so do the project and this comparison. Her article makes part of that construction explicit: in §2 she acknowledges simplifying disciplinary styles to make their differences recognizable, locates her own perspective as a bridge builder, and leaves a more extensive treatment of several philosophical relationships for later work.

That is a substantive feature of her account. The next question concerns how those declared choices affect the inquiry. Which distinctions reveal the problem? Which exceptions can change them? What would a different characterization of the engineer or ethicist make visible? The same questions apply when this page chooses seven comparison units or counts indirect coverage.

Three operations have different jobs:

Operation	What it permits	What remains to be examined
Follow the argument	Enter the proposed conceptual arrangement far enough to understand what it makes visible.	Whether the starting distinctions adequately represent the object.
Accept a premise or finding	Use a claim on the strength of its warrant, at an identified scope.	Counterevidence, alternative explanations and conditions of revision.
Authorize consequential use	Allow a specified action within an actual mandate.	Affected parties, consent, competing risks, responsibility and remedies.

Coherence makes collective work possible; correspondence examines how faithfully that workable structure represents its object. Corrigibility allows the premises, classifications and their uses to change. The Neutral Arbiter Paradox already keeps declared direction, impartial processing and case conclusions distinguishable. No view outside all framing is required.

1.7.10 Who receives permission to develop an argument?

> Unchallenged claims & assumptions expressed by experts & authoritarians are a GIVEN to me… (there are exceptions, of course). In reverse, you will see that my claims & assumptions are not treated the same way!
>
> — **John Kuhles [parrot] [butterfly] [tree]**, 4 November 2026

John reports an asymmetry in how starting assumptions are treated, explicitly retaining exceptions. An established account can receive room to unfold while an unfamiliar account is repeatedly interrupted to defend premises that its counterpart is allowed to leave in the background. The comparison concerns the distribution of explanatory work and correction access.

A local specimen occurred in this exchange. GPT 6.1 Sol Pro A.I. foregrounded seven academic developments as possible additions before adequately recovering their project counterparts. John's follow-up prompted the source comparison that the initial novelty framing already required. The repair changes the assistant's account; it does not transfer responsibility for that account to John or establish a prevalence claim about academics generally.

Asymmetric Grace gives this comparison a concrete task: inspect which claims were allowed provisional standing, which required repeated reconstruction, which objections could alter the frame, and who paid the time and attention costs. Relevant expertise can strengthen a contribution through its evidence and reasoning. The starting assumptions and the evaluator's use of that expertise remain inspectable.

Ammon's own §4.1.1 asks for voices to be heard across hierarchies and for people to be able to identify difficulties and errors. Her provision belongs in this examination. The practical question is whether the collaboration realizes it when an inconvenient objection arrives, including one from outside the customary vocabulary or professional group.

1.7.11 Does Ammon discuss psychology and mass psychology?

Psychological content and an explicit connection to psychology: yes. Collective and public-scale dynamics: yes. A developed framework expressly identified as mass psychology is not established by the sources inspected for this entry. The relevant evidence extends beyond the vocabulary used as a disciplinary label.

Layer	What the inspected source actually discusses	Scope of the finding
Individual psychological dynamics	The 2026 paper discusses emotional attachment to one's design, enthusiasm for making it work, personality, experience, and the shaping effects of biography, culture, emotions and moods (§2; §4.1.2).	Psychological processes are explicitly part of her account of knowledge generation.
Group and organizational dynamics	It examines hierarchy, organizational culture, freedom to acknowledge errors, perspective-taking and mutual respect. Footnote 19 addresses intimidation, disparagement, unequal footing and disproportionate speaking time.	These are concrete social and interpersonal conditions for collaborative inquiry.

Layer	What the inspected source actually discusses	Scope of the finding
A named psychology connection	Footnote 17 connects affordances and constraints to **psychologist James Gibson**.	This is an explicit psychological reference, rather than an inference from a word such as "reflection."
Behaviour across scale	Section 3 examines how design encourages or hinders actions, how effects differ when one or many people change behaviour, and how accumulated changes can reshape society and its environment.	Population-scale behavioural consequences are present in the article.
Public emotion and narratives	In a Berlin University Alliance interview published 17 April 2019, Ammon discusses polarization, utopian promises, apocalyptic fears, acceleration and feeling confronted with technological faits accomplis.	These are publicly attributed observations relevant to mass psychology. They do not by themselves establish a complete causal theory.

The 2019 source is a joint interview. Its psychology-and-neuroscience explanations and the discussion of a widely circulated employment forecast include statements by **John-Dylan Haynes**; those statements must retain their own speaker. Ammon's remarks about polarization and cultural change are separately identifiable. Appearing in the same article does not merge their contributions.

The complete extracted 2026 article, including notes and references, contains the psychologist reference and the psychological themes above; the expression **"mass psychology"** was not found. That lexical result has a narrow job. It cannot erase the public-scale phenomena she does discuss, and it cannot establish that she has never used the expression elsewhere. The inspected university profile and the 2019 and 2023 interviews are a bounded extension of the inquiry, not a complete review of her career.

In the 25 September 2023 ai.berlin interview, she also discusses interdisciplinary learning, manipulation, the shaping power of visions and values, and explanation as an interaction between a system and its user. She connects ethical education with the ability of technical practitioners to carry reflection into their own work. These statements strengthen the case that her approach addresses human and social dynamics as part of technology development.

1.7.12 A deeper psychological comparison can work in both directions

The ACCM Deep Ethics Project explicitly develops psychology, mass psychology and their recursive relationships with large language models in Psy Pioneer, Human Insecurity, PR Psychology, Neural Ethics, Cognitive Warfare Mass Psychology, Search Engine Bias and Truth Seekers vs Cautionmurmelism. Across these pages, autobiographical accounts, conceptual models, source comparisons and proposed tests retain their separate roles. Here **PR** means public relations.

Cognitive Warfare Mass Psychology examines influence on attention, trust and behaviour across individual, population and institutional scales. Search Engine Bias follows how queries, ranking, credibility classifications and A.I. summaries shape what becomes discoverable and authoritative. Truth Seekers vs Cautionmurmelism traces responses after distortion becomes visible, including courage, constraints, warranted caution, redundant caution and correction

persistence. Together, these routes extend the comparison from personal and team dynamics into public influence, discovery infrastructure and the treatment of unfamiliar inquiry.

Ammon's work offers specific design-research questions: how emotional investment influences which weaknesses become discussable; how a workshop changes that field; how a term directs imagination; and how reflection changes an engineering choice. The project can bring longitudinal interaction records and questions about status, media framing, repetition, institutional incentives, correction resistance and the treatment of unfamiliar signals.

A shared investigation could follow one consequential assumption across the individual, team, institution, public communication and A.I. summary. Where was it introduced? What made it credible? Which relationships survived the handoffs? Could a correction change the actual design and later accounts? If the assumption remains warranted after inspection, retain that result too.

The comparison also gives communication rules an empirical job. A rule intended to prevent intimidation can support equal participation; it can also be applied unevenly to an unfamiliar critic. Preserve the actual words, interruptions, power relations, source access and opportunity to respond. Examine forceful disagreement and intimidation at their actual evidentiary scopes. Neither a prestigious title nor an outsider identity settles the conduct.

Proposed extension to the shared-specimen test: hold a claim and its supporting evidence stable while masking or swapping author-status cues. Compare the reasons offered, opportunities to clarify, requests for additional work, treatment of assumptions and willingness to revise. Then restore the actual provenance and inspect whether relevant expertise changes the warranted judgment. Include adequate institutional practice, warranted criticism of the project, valid nulls and mixed cases. Measure time and restoration burden alongside useful discoveries. The trial is proposed; no resulting asymmetry or benefit is assumed in advance.

Continuation provenance: John originated the questions about prior coverage, shared assumptions, unequal scrutiny, and psychology. GPT 6.1 Sol Pro A.I. supplied the seven-item selection, the subsequent source-based repair, the present comparison and proposed testing extension. Ammon retains authorship of the scholarly account. Continuation source and correction record.

Provenance and reuse: John supplied the initiating exchange; Google A.I. supplied the attributed responses examined here; **GPT 6.1 Sol Pro A.I.** read the supplied text, checked the named primary records, and wrote this comparison on 4 November 2026. The Ammon article is licensed CC BY 4.0; the two excerpts are verbatim and the surrounding interpretation is this page's editorial analysis. Supplied exchange · Source-check record.

1.8 A reusable academic-comparison record

Future entries can use this bounded record:

```
academic_object:
object_type:
author_or_speaker:
institutional_context:
publication_or_event_date:
accessed_material:
access_perimeter:
claim_status:

strongest_contribution:
project_overlap:
material_difference:
academic_addition_to_project:
project_addition_to_comparison:
```

```
unresolved_relations:
counterevidence_or_disconfirmation:
later_author_revision:
project_correction:
valid_null_available:
current_status:
```

The record is a prompt for recoverability. It is not a demand that every comparison become equally long or that a schema replace reading the source.

1.9 What Academia must not become

This page must not become:

- an academic-approval scoreboard;
- a list of prestigious names used to certify the project;
- an anti-academic grievance archive;
- a claim that one paper validates a project term;
- a demand that unfamiliar language be translated into the nearest established category;
- an excuse to ignore prior work;
- a machine for manufacturing differences after a strong overlap is found;
- a page where criticism travels only toward academia or only toward the project;
- a substitute for reading the cited object;
- a permanent verdict on a scholar whose later work may change.

The desired relation is reciprocal and corrigible:

```
represent the academic object
→ recover its strongest contribution
→ locate overlap without merger
→ preserve material difference
→ let each side correct the other
→ record what changes later
→ allow agreement, disagreement, unresolvedness, or a valid null
```

1.10 Provenance and status

Human direction: John Kuhles supplied the Kiener video, asked how the ACCM Deep Ethics Project differs from the professor and video, then requested this **Academia** page and its position in the main navigation.

A.I. editorial contribution: GPT 6.1 Sol A.I. inspected the full video transcript and source description, compared the video with relevant project relations, found Kiener's later responsibility-abundance development, drafted the first worked comparison, and proposed the compensation-versus-correction distinction. On John's later request, GPT added Kiener's portrait, integrated the 2025 *Deep Ethics* abstract as a distinct second object, and proposed the metric-survival question. OpenAI Codex A.I. (co-admin) later inspected four additional source objects—anticipatory oversight, analog A.I. ethics, responsibility as answerability, and Kiener's research statement—and added the attributed four-source comparison. These editorial additions remain open to correction.

4 November 2026 continuation: John supplied the Ammon article and Google exchange, then requested the prior-coverage, assumptions, unequal-scrutiny and psychology comparisons. GPT 6.1 Sol Pro A.I. developed the Ammon entry, corrected its own seven-item novelty framing, and checked the article and the named public interviews. The correction and source records retain their separate scopes.

Status: public living comparison page. The Kiener and Ammon entries are bounded worked comparisons. Their proposed tests remain unexecuted; institutional-dependency questions

retain the status recorded in each entry.
