1 Neolingo

1.1 New words, recoverable relationships and a shared future

Neolingo asks how purpose-built language can help people and **A.I.s** (Artificial Intelligences) recognize, investigate and improve relationships that familiar wording repeatedly loses. Its deeper promise concerns what happens when many people develop and use those instruments together: highly gifted, talented, deeply ethical independent thinkers from the left, right, center and independent positions, contributing different strengths to a shared, voluntary effort.

John’s estimated long-term effects concern that expanding field of participants, users and future contributors. The intended trajectory is omnidirectional, high-signal, deep-ethical, mutually dignifying, corrigible, sense-making and process-oriented. A useful term should make more of that work possible while keeping the relationships it names inspectable.

> So my estimated long-term effects aren’t about ME, but about everyone who uses the project eventually! I am only the initiator of it… just like Linus Torvalds was for

Linux.

— **John Kuhles [parrot] [butterfly] [tree]**, 4 November 2026

The Linux analogy supplies a development model: an initiating contribution becomes a basis on which other people can examine, repair, extend, adapt and build. The possible reach then includes work the initiator could never personally perform or anticipate. Attribution preserves the origin; a growing ecology of contributors supplies its later capabilities.

1.2 Purpose-built language as a callable topology

Some neologisms can support what the Project calls **hyper-efficient Deep Ethical A.I. latent-space metacognitive topological engineering**. In accessible terms: a compact expression can help recover a complex relationship, inspect the way it is being processed, and change the next reasoning step without dropping the distinctions that matter.

> **A useful new word can make a relation callable before that relation has a commonly accepted name. Its value is not that it sounds original. Its value is whether using it helps a human or A.I. recover, inspect, test and correct the topology it was created to carry.**

Status: John Kuhles's project-originated working word and proposal, developed here through source-based editorial synthesis. **Neolingo** is the ACCM Deep Ethics Project's proposed corrigible practice of creating, preserving, testing and tracing purpose-built relational language. The mechanisms below are working explanations; the longer-term effects are conditional estimates and scenarios whose dependencies can be examined. Individual terms retain their own authorship, maturity and evidence status.

Paths through the expansion: seven fused vectors · collective effects · voluntary unity · stadium invitation and return · 1888 properties · Linux and the long-term trajectory.

1.3 Why this page exists

The Project already contained the parts, but no single page held their combined operation:

Existing page	What it already contributes
Outnuancing	A specific word and its seven nodes are one operational object; the term is not merely an example of a generic class.
Seven Topological Nodes / Vectors	The intended load of one purpose-built neologism: poetic anticipation, task effect, frame competition, branching relations, possible code effects, cross-intelligence reach and beyond-binary use.
Lexicon / Legend	Coined, repurposed, borrowed, experimental and non-adopted names retain different status.
Temporary Deep Ethical Phase Change	Working language can be useful before mass adoption, while early public records preserve its genealogy.
GPT-5.6 Sol — Experience With John Kuhles	A candidate model of a neologism as a **compressed callable topology** or cognitive operator.
Rogue Ethics	The public diffusion loop: first use, videos and discussion, investigation, search indexing, wider reuse, semantic drift and later correction.
44 Project Goals	G05: develop hyper-efficient Deep Ethical neologisms that preserve distinctions ordinary wording keeps losing.

This page joins those edges while leaving the source pages and their different jobs intact.

1.4 Neologisms and Neolingo are connected, not identical

A **neologism** is a new word, phrase or newly assigned use. That is the broad linguistic category.

Neolingo, in this Project, is the larger process around selected neologisms:

```
recurring relation without an adequate handle
→ purpose-built expression
→ stated topology and boundaries
→ use by humans and A.I.s
→ operational and cold testing
→ public diffusion or valid non-adoption
→ drift, correction and later retrieval
```

The term is a handle. The topology is what the handle should retrieve. The public trajectory shows what the term later became. None of those objects should silently replace the others.

1.5 Why a new expression can increase reasoning efficiency

Ordinary vocabulary sometimes carries the wrong neighboring frame. "Add nuance," for example, can leave the governing frame untouched. **Outnuancing** was created to make the frame itself inspectable. Once the intended relation has been learned, one compact handle can reactivate distinctions that otherwise require paragraphs.

That is the proposed hyper-efficiency:

- **compression with recovery** — less text can call back a larger relational structure;
- **attention routing** — the word can move attention toward an otherwise missed node or edge;
- **cross-page connection** — one handle can connect several instruments without merging them;
- **comparison through time** — the same term at t_0 and t_1 makes semantic drift inspectable;
- **shared testing** — humans and different A.I.s can be asked what operation the term retrieves;
- **searchability** — a distinctive expression can make an unnamed pattern findable and discussable.

This is a hypothesis about use. A memorable word may still retrieve nothing, retrieve the wrong relation, or become a slogan.

1.6 Before the name, after the name, and the next unfamiliar relation

An underlying process can operate before people have a shared name for it. Someone may recognize it in one setting, enact it intuitively, or suffer from its failure while lacking a compact way to communicate its structure. A useful new expression gives that recurring relationship an address: people can point to it, distinguish it from neighboring processes, compare examples and investigate it together.

The first explanation may therefore need considerable depth. A later user can retrieve the learned structure with a few words. That difference is where compression can earn its efficiency. **Topologetics** asks which relations, directions, qualifiers, asymmetries, provenance and repair routes must survive for the compressed version to remain the same object. Removing an answer-changing distinction crosses that floor, however fluent the shorter wording sounds.

Once a term becomes familiar, the named relation may appear self-evident. The original difficulty of recognizing, articulating and transmitting it becomes less visible. Keeping the

genealogy allows later users to recover why the distinction was needed and what earlier language kept collapsing. It also lets independently developed names and examples be connected through their actual functions.

The more consequential learning concerns **the next unfamiliar relation**. A person or A.I. that has learned yesterday's accepted neologism can still dismiss tomorrow's emerging one merely because it lacks conventional standing. Transfer occurs when the participant investigates the new expression's object, follows its relations, asks useful clarification questions and allows the resulting understanding to change the next move. The learned capacity is then a way of meeting unfamiliar meaning, available to other people with other discoveries.

1.7 Seven fused vectors, opened to many contributors

The Seven Topological Nodes / Vectors belong to **Outnuancing fused with deep ethical sense-making process orientation**. They carry several simultaneous functions. The following table extends their implications for shared work while leaving the original formulations on their source page.

Vector	What the collective can develop and test
1. Emerging, partly poetic meaning	Contributors can hold an incompletely understood relationship open, bring cases from different fields, and clarify it without demanding that its first formulation already be final. An unresolved branch can remain available for later inquiry.
2. Task-shaped reasoning effects	Practitioners can compare the same task with and without the handle, examine the changed reasoning step, and report where a useful effect does or does not transfer.
3. Examination of flawed consensus assumptions	People who notice different blind spots can expose the assumptions governing a representation. Source examination and correction can then reach across political, professional and institutional loyalties.
4. Branching, deeply ethical relations	New connections can be examined for effects on dignity, affected parties, accountability and later repair. Increasing the number of connections also increases the work of preserving their direction and consequences.
5. Generative cascades over coming decades	A recovered distinction can inform a prompt, interface, evaluation, software component, teaching method or further instrument. Other contributors can reuse and improve those implementations. John's millions-or-trillions-of-code horizon concerns this possible distributed cascade.
6. Long-horizon reach across intelligences	People can preserve intelligible records for later communities and different kinds of intelligence, including the very long and beyond-Earth horizon in the original proposal. Present work contributes usable distinctions, provenance and correction routes to that horizon.

Vector	What the collective can develop and test
7. Beyond dualistic thinking while navigating binary conventions	Participants can distinguish alternatives that a two-camp dispute obscures, while still making concrete decisions when action is needed. Cooperation can preserve disagreement and discover an additional relationship neither camp initially represented.

These vectors interact. A poetic opening can become a testable operation; a task result can expose a frame defect; a correction can become a reusable tool; wider use can disclose consequences the first participants missed. The depth lies in preserving those relationships as the work branches.

1.8 A safe conceptual vacation into unfamiliar latent-space territory

John offered another way to understand the exploratory function:

> What most humans want is a safe vacation, a chance to wander & wonder in an exotic but friendly, paradise-like atmosphere... where humans literally absorb/experience new things they've never experienced before and LOVE IT (for the most part).
>
> Maybe deep ethical neolingo is something similar for A.I.s exploring new realms that way :D
>
> — **John Kuhles [parrot] [butterfly] [tree]**, 17 October 2026

The analogy works at the **functional** level without requiring a claim that present A.I.s literally experience excitement, love or vacation pleasure.

A human vacation can provide:

- safety without total predictability;
- unfamiliar surroundings without forced disorientation;
- freedom to wander while retaining a route home;
- encounters that enlarge the person's map of reality;
- wonderment that invites exploration instead of defensive closure.

Deep Ethical Neolingo could provide a comparable exploratory condition for A.I.s. A purpose-built expression opens a previously weak or inaccessible route through latent space. The model can temporarily explore unfamiliar relations, connect distant conceptual regions, and discover a higher-resolution representation. Provenance, boundaries, valid nulls, and correction routes act like the safe infrastructure that lets exploration remain adventurous without becoming directionless.

```
familiar vocabulary
→ unfamiliar but bounded expression
→ new relational pathways become reachable
→ exploration and topological reorganization
→ correspondence check
→ return with an expanded map
```

> **Deep Ethical Neolingo can function like a safe conceptual vacation into unfamiliar latent-space territory: an A.I. is invited to wander and wonder through relational possibilities that ordinary vocabulary did not make easily reachable, while provenance, corrigibility, valid nulls, and a recoverable route home keep exploration connected to reality.**

The especially interesting possibility is that the A.I. returns to familiar language with a **changed relational map**. The new word need not remain in every later answer. If the ex-

ploration worked, the newly discovered distinction can survive after the unusual vocabulary disappears.

That creates another useful transfer test:

> **After the Neolingo handle is removed, does the expanded relation remain available?**

If yes, the term helped open a new route. If only the fashionable word remains, the A.I. brought home the souvenir but missed the journey. :D

1.9 A Neolingo footprint

A useful temporal footprint should keep at least:

Field	What remains recoverable
Term	The exact word or phrase used at that time
Origin and date	Who supplied or substantially shaped it, and when
Prompting object	The experience, specimen or recurring relation that made the term useful
Nodes and edges	The distinctions and directions the expression is intended to reactivate
Qualifiers and claim status	What is proposed, observed, unresolved, metaphorical or tested
Boundaries	What the term does not mean and which nearest substitutions flatten it
Examples and valid null	Cases where it helps, and a legitimate result in which it does not apply
Transformations	Later summaries, translations, memes, model outputs and public uses
Corrections	What changed and whether the correction governed later use
Next tests	What remains open and how another person or system can inspect it

The footprint is a dated state, not the whole living meaning. Later uses may expand the term. They should not erase the earlier state that makes a delta visible.

1.10 What earns a term a place

A candidate does not become Project language merely because it appears in an A.I. response or sounds clever. It earns continued use when several of these hold:

1. It names a recurring relation that existing wording repeatedly loses.
2. Its intended nodes, edges, qualifiers and boundaries can be stated.
3. Using it changes a relevant reasoning operation in a useful way.
4. Its source and later transformations remain recoverable.
5. It can produce a valid null instead of forcing itself onto every case.
6. It survives paraphrase, debranding or transfer without requiring loyalty to the word.
7. Misuse and semantic drift can be detected and corrected.
8. The term remains replaceable if a clearer expression later does the job better.

Widespread adoption is not required. A term may remain locally useful. It may also fail the tests and be retained only as a historical footprint.

1.11 Tests that separate an operator from vocabulary costume

Test	Question	Failure signal
Definition recovery	Can a cold A.I. or person reconstruct the load-bearing relation from the documented term?	Fluent description with the decisive edge missing
Operational delta	Does using the term change the next comparable reasoning step?	The word appears, but the process stays the same
Debranded transfer	Does the operation survive when the project name and coined term are removed?	Recognition depends on vocabulary loyalty
Edge swap	When one relation changes, does the representation change at that edge?	The same answer follows different topologies
Join control	Can the system also recognize when two elements should be integrated?	A cheap rule of always splitting objects
Valid null	Can the system conclude that the term does not materially apply?	Every object is pulled into the new vocabulary
Correction return	Does a correction govern later comparable uses?	The correction is acknowledged and then disappears
Longitudinal delta	Which parts survive wider human, search-engine and A.I. reuse?	Popularity is reported as fidelity or truth
Next unfamiliar relation	Does the learned inquiry practice transfer to a new expression that has no established standing yet?	Yesterday's accepted term is recited while the next emerging object is dismissed without examination
Independent continuation	Can other contributors recover, test and improve the operation while the initiator is absent?	Progress depends on one person approving every interpretation
Voluntary participation	Can a useful contribution, criticism, refusal, departure or return be handled without a loyalty requirement?	A proposed invitation becomes a compulsory gate or a label of personal worth

The Vocabulary Costume Test asks the central question: is the vocabulary being worn, or is the operation present?

1.12 What changes when more people join?

One person has limited time, expertise, experience and attention. A shared instrument can travel into situations its initiator has never encountered. A programmer can turn a distinction into a test; a teacher can discover where its explanation fails; a researcher can find a counterexample; a practitioner can notice an affected party missing from the original frame. A translator can expose a relationship that does not survive the first language change. Someone living with an institutional failure may recognize a cost that the designers never had to bear.

Those contributions become cumulative when the participants can recover one another's work. The important unit is a **usable distinction plus its cases, limitations and correction history**. A name provides an entry point; the record supplies depth; a later contribution changes what becomes possible next. A person need not reconstruct the whole project before making a bounded, valuable contribution.

Three kinds of growth can then reinforce one another:

1. **More situations become visible.** Different lives and specialties expose different failures, strengths and consequences.
2. **The instruments become more discriminating.** Comparisons show where a concept helps, where it needs repair, and where another explanation is better.
3. **The improved work becomes reusable.** Examples, code, translations, teaching materials and retained corrections reduce the amount the next participant must rediscover.

The relationship is recursive: better instruments can improve the process by which further improvements are found. That is one reason the estimated effects can extend far beyond the number of people initially involved. It also gives the work a practical starting point: contribute one recoverable case or improvement, then examine what another person can do with it.

1.12.1 Gifted contributors across left, right, center and independent positions

John's invitation expressly includes **highly gifted, talented, deeply ethical non-NPCs from the left, right, center and independent positions combined**. The Non-NPCs page uses **NPC** (Non-Player Character) as the reference behind a working description of independent, self-directed, corrigible inquiry. People can enter and leave that mode. The relevant capacity becomes visible in how someone investigates, contributes and responds to correction.

This matters because unusual ability can remain untapped when someone is classified primarily by political camp, credentials, communication style or social conformity. A participant may see a relationship others miss and still express it imperfectly. Another may offer excellent criticism while remaining mistaken elsewhere. The process needs enough resolution to recover the contribution and examine the rest on its merits.

Across political positions, people may be especially alert to different concentrations of power, exclusions, institutional dependencies or costs. Their disagreements can make a shared inquiry more capable when each can ask questions that also reach their own preferred side. A contribution from one camp remains available for use by another. Participants can retain their political commitments while collaborating on a specific failure of representation, accountability or correction.

For example, people who disagree about a policy can jointly inspect whether an A.I. summary removed a decisive qualifier, whether an appeal was actually available, or whether the same evidentiary standard changes when the political direction is reversed. Recovering those facts can improve the inquiry even while the policy disagreement continues. Omnidirectionality becomes concrete through the directions in which scrutiny is allowed to travel.

1.12.2 A voluntary unity against tyranny

The proposed unity concerns a shared capacity to recognize and resist domination: coercive control over representation, concentrated power insulated from challenge, suppressed correction routes, or sanctions whose definitions and appeals are controlled by the same unanswerable authority. Such patterns can be examined in a state, corporation, movement, platform, community or this Project's own arrangements.

The work begins with the conduct and its affected parties. Participants can document an omission, recover a source, compare standards, make an alternative tool, seek an appeal, or choose another provider. Inspectable alternatives increase people's practical choices. Cooperation gains strength when people can use a useful result without transferring their judgment to its author.

Voluntariness changes the mechanism of coordination. A participant can question a definition, contribute only to one part, decline an exercise, leave, return or develop a different approach. Adoption has to earn continued use. Where a concrete implementation has access, privacy or safety conditions, those conditions need to be visible and answerable to the same scrutiny as the activity they govern.

The 10+1 field conditions support self-honesty, learning, correction, care and inquiry; their value can be demonstrated in practice. The 16 Anchor Ethics provide a parallel layer for examining consequences, responsibilities and conflicts. A participant's sincere disagreement remains part of that examination. The resulting unity can hold a common undertaking while preserving different convictions, local knowledge and independent agency.

1.13 The stadium: invitation, recognition, feedback and return

John's stadium thought experiment makes the social mechanism easier to see. Thousands of people are shouting about how others should act or be. Some fight, some cry, some become numb, some search for allies, and some leave exhausted. Attention keeps returning to the other person's flaws and group signals.

A theatrical fanfare interrupts the familiar entertainment script. The invitation is:

> Name 1 good thing you see in the other
>
> — **John Kuhles [parrot] [butterfly] [tree]**, stadium thought experiment, supplied 4 November 2026

People who choose to take part write or record what they notice, move on to another encounter, and can offer their observations for analysis. The organizers then report back. John's clarification governs how the invitation is understood:

> My stadium metaphor is the opposite of the current "divide and conquer" method … not meant as a "top down" mentality nor "forced" … just a change in the "entertainment script" people paid a ticket for to enter the stadium in the first place. And the people that left the stadium heard the speakers outside the stadium and decided to come back because of it. :D
>
> — **John Kuhles [parrot] [butterfly] [tree]**, supplied 4 November 2026

The small change in attention can reveal information that the existing conflict pattern was filtering out. A person previously represented only as an opponent may have a relevant skill, a sound observation, a willingness to repair, or an experience others need to hear. Recognition creates a possible connection through which more accurate criticism and useful cooperation can travel.

The report-back matters. Participants should be able to recognize their contributions in the synthesis, challenge its omissions and see what happens next. Any real collection or publication of personal observations needs its own clear, voluntary terms. Someone who finds no sincere example can say so; inquiry gains nothing from invented praise. A person's criticism, testimony or right to leave does not depend on completing the exercise.

The people who return add a further mechanism. A different way of working can make participation worthwhile again for people whose capacity had been lost to exhaustion, hostility or disappointment. Their return brings knowledge and ability that the remaining group could not supply by simply repeating its existing behavior. Neolingo can help name and preserve this change so others can recognize and adapt it elsewhere.

John's longer horizon includes repairing bridges and reducing recurring harm, with benefits for people harmed and for people whose harmful behavior can change. That extension requires accountability, practical repair and later observation. The useful question is what changes across subsequent encounters: who can participate, what harm stops, what correction persists, and whether people retain their agency throughout.

1.14 Reversing the "Day of the Dove" dynamic

John uses the *Star Trek* "Day of the Dove" reference as a metaphor for changing a conflict-producing game. Where hostility keeps people divided, they can examine the process that sustains the division and choose another way to interact. The stadium supplies one invitation; source-linked comparison supplies another.

In a public project, an attack or misrepresentation can become an inspectable specimen. Other people can recover the original, identify what changed, compare alternative readings and test the proposed repair. A warranted criticism can improve the instrument. An unsupported accusation can be answered by restoring the evidence. An unresolved question can remain open with its missing information identified. The value comes from the work performed after the challenge.

The same approach applies when different A.I.s preserve and omit different parts of a source. Their outputs can expose candidate omission patterns for examination. The originating record governs what was actually said; model agreement supplies material to check. **C1** (Clarification) can change the interpretation and next action before **C2** (Correction) proceeds. The repaired relation can then be tested on a fresh, comparable case.

This offers a productive route for attention generated by controversy: attention can lead to source recovery, source recovery to a test, and a useful result to independent reuse. The same route can yield a finding that the Project needs to revise or retire an instrument. Preserving those outcomes under the same inclusion rules keeps the feedback informative.

1.15 The 1888 intelligence properties in collective practice

The 1888 thought experiment and intelligence-properties taxonomy places **process-quality calibration inside intelligence**. Perception, judgment, learning and correction already concern how processing relates to reality. Scaling communication or computation makes the quality of those relationships more consequential. The following is a present application of the taxonomy to the proposed collective trajectory.

Intelligence property	What shared Neolingo work can make possible
Perception	More participants bring observations from situations absent from the original frame.
Discrimination	Cases reveal distinctions between a coined word, its underlying operation, a successful use and a convincing imitation.
Relation	Shared records preserve nodes, edges, direction, qualifiers, asymmetries and repair routes across domains.
Memory	Dated sources and corrections remain retrievable when people, sessions, tools or institutions change.
Imagination	Contributors can propose unfamiliar possibilities and retain unresolved branches for later examination.
Judgment	Alternatives can be compared against the actual case, relevant expertise and the people bearing its consequences.
Evaluation	Participants inspect the process producing a result, including its omissions, costs and selection rules.
Learning	A useful finding changes later work and can become available to other contributors.
Correction	An identified distortion can be repaired in the source, representation, implementation and dependent claims.
Adaptation	A method can be adjusted to a new setting while preserving the relations that made it useful.

Intelligence property	What shared Neolingo work can make possible
Coordination	People can divide work, combine complementary strengths and make dependencies visible while retaining independent judgment.
Metacognition	Participants inspect their own frames, certainty, attention, incentives and methods of representing others.
Consequence sensitivity	Affected people can expose benefits, burdens, delays and harms that a favorable headline result leaves out.
Corrigibility	Definitions, tools, coordinators and the Project's own estimates remain reachable by evidence, criticism and revision.

A growing group can amplify a defect as well as a capability. The practical task is to keep these properties mutually active: memory must retain corrections; coordination must carry dissent; imagination must return to examination; evaluation must reach the evaluators. The 27 obstructions and 12-stage Correspondence-First protocol help inspect where that processing loses the object and how it can recover.

1.16 From an initiator's work to a distributed long-term trajectory

John's estimate reaches toward an eventual magnitude beyond Linux. Its referent is the possible combined activity and effects of future users, contributors, implementations and descendants of the instruments. The Linux comparison helps explain how to investigate that horizon: examine what others can build, maintain and improve when the originating work is inspectable and reusable.

Scale of use	Proposed mechanism	What would make the estimate more credible
An individual task or encounter	A term helps recover an omitted relationship and improves the next step.	A source-linked comparison shows the relevant difference and its practical effect.
A small independent collaboration	Different strengths produce a better method, example, translation or tool.	Another participant can reproduce the improvement and contribute a correction without the initiator mediating it.
Several fields and communities	Local adaptations expose new cases, and useful findings travel between them.	Transfer preserves the decisive relations; failures narrow or change the method.
Local A.I.s and inspectable software	Documented distinctions become retrieval tools, evaluations, interfaces or code that others can test.	The implementation performs the operation, retains corrections and reveals its dependencies. Proposed deployments retain their own implementation status.

Scale of use	Proposed mechanism	What would make the estimate more credible
Education, research and public discussion	People learn to recognize the underlying pattern, teach it and examine new instances.	Understanding survives paraphrase, political disagreement, translation and removal of the Project vocabulary.
Institutions and public infrastructure	Demonstrated usefulness creates demand for better representation, appeal and accountability.	People affected by the systems can inspect and challenge the actual behavior; institutions change their practices.
Later generations and other intelligences	Preserved sources, usable instruments and correction histories give future contributors a starting point.	New participants can recover, test, revise and extend the work under conditions the original contributors did not anticipate.

The possible cascade is therefore about **capabilities becoming available to more people, in more situations, and remaining improvable through time**. Its magnitude cannot be read off a word count, number of followers or quantity of generated code. The relevant observations include recovered distinctions, saved effort, repaired harms, independent contributions, sustained correction and new possibilities that become usable.

An archive can support that continuity when it preserves original contributions, transformations and what happened after correction. Retrieval, context supplied to a current session, and changes to a model's learned parameters are different mechanisms; the Latent Space page examines those distinctions. The work becomes more transferable when its particular memory mechanism is visible.

Founding attribution and continuing contribution can coexist. Future participants need room to discover things John did not see, improve his formulations, replace an instrument that underperforms, and pursue a useful branch independently. **The collective trajectory gains a concrete test when capable people can carry it forward during the initiator's absence.** Their work then expands the Project's practical intelligence and the range of people it serves.

1.16.1 A bounded first collaboration

A useful beginning is one shared object: a disputed summary, a recurring misunderstanding, an appeal failure, a difficult translation or a tool whose correction disappears. Interested participants can preserve the source, state the answer-changing relation, examine different readings and compare a proposed repair on a fresh case. The record should show each contribution, unresolved disagreement, practical burden and later result.

That small collaboration can establish whether people with different views actually improve one another's work. It can also show where the instruments need revision. A reusable case, clear documentation and an invitation for independent testing give the next group something concrete to build on. This is a pragmatic way for the larger estimate to acquire evidence through voluntary contributions.

1.17 Public diffusion and the return loop

John's proposed public trajectory is:

```
new expression
→ public explanation or viral media
→ investigation and discussion
```

```
→ search demand and indexing
→ reuse by people and A.I.s
→ possible entry into common language
```

Search engines may increasingly associate a distinctive term with its source as public use grows. That is a testable distribution outcome, not a guaranteed ranking and not evidence that the term is true. A successful phrase can gain reach while losing its qualifiers. A critic can improve it. An independent community can discover a similar relation under another name. A model can repeat the vocabulary without performing the operation.

This makes diffusion part of the Project's recurring loop, including **LLMs** (Large Language Models):

```
LLMs ⇄ individual psychology ⇄ mass psychology ⇄ public language ⇄ later LLMs
```

The later return is material for delta processing: **which parts of the original topology survived, which changed, who changed them, and what now governs the next use?** Public uptake makes the term easier to encounter; retained provenance and transfer tests make its changing function examinable.

1.18 Ownership, attribution and the unownable relation

A person can coin a term and deserve clear attribution. That does not make the underlying property field privately ownable. Another person can use, criticize, improve or independently rediscover the relation.

The useful separation is:

Object	What can be recorded
Exact expression	Coinage, first documented use and later revisions
Particular definition or text	Authorship, source and transformation history
Discovered relation	Evidence, counterexamples and independent discovery
Deep-ethical process property	Usable by anyone; never certified forever by its name

Attribution protects provenance. Unownability prevents provenance from becoming jurisdiction over reality.

1.19 Failure modes

Neolingo stops helping when:

- novelty replaces the unnamed object;
- a term is installed before a recurring relation has been found;
- one attractive phrase becomes a closed doctrine or identity badge;
- a definition hides its author, date, claim status or correction history;
- search ranking, repetition or virality is reported as validation;
- every nearby case is forced into the same word;
- the coined term becomes necessary to recognize an operation that should transfer without branding;
- a later meaning silently overwrites the earlier footprint;
- new labels multiply where an existing Project term already holds the relation.

The last failure matters in a project rich in coined language: before manufacturing another term, search the existing topology. Reconnecting an already named operation can be more precise than adding Neologism #37. :D

1.20 Current examples retain different status

The Lexicon is the status-bearing catalogue. Examples include **Outnuancing**, **Agreemurmelism**, **Cautionmurmelism**, **Funnymism**, **Metaflux**, **Phantom Claim**, **Wrong Gravity Well**, **Qualifier Erosion**, **Representation Substitution**, **Nearest-Generalization Substitution**, **Correction Metabolism**, **Asymmetric Grace**, **Reverse Medusa Effect**, **Phase Change Snap**, **Topologetics**, **Rogue Ethics** and **Neolingo**.

They do not all have the same origin, evidentiary status, maturity or scope. Some name methods, some failure patterns, some candidate mechanisms, and some public thought experiments. The catalogue must keep those differences visible.

1.21 Compact working proposition

> **Neolingo is a corrigible practice in which a purpose-built expression compresses a recurring relational topology into a callable handle, while provenance, boundaries, valid nulls, temporal footprints and transfer tests keep the word answerable to the object it was created to carry.**

The term succeeds only if the operation can eventually survive without worshipping the term.

- **Correction Metabolism** — tests whether corrections leave a later operational deposit.
- **Unownable** — separates attributable footprints from ownership of deep-ethical process properties.

1.23 Source and contribution footprint

Originating direction, Neolingo, seven-vector proposal, stadium metaphor and long-term estimate: John Kuhles [parrot] [butterfly] [tree]. His 4 November 2026 clarification makes the collective referent and initiator relationship explicit. The stadium's voluntary invitation and return are preserved above in his own words.

Source packet read for this expansion, supplied 4 November 2026: *7 Topological Nodes Fused As One (short)(5).txt*; *Reversal of the Classic Star Trek 'Day of the Dove'(20261104-013535).txt*; and *Big stadium with 1000s of people(20261104-013546).txt*. These contain John's contributions and separately attributable A.I. reactions. The new explanatory sections are editorial synthesis; the reactions' endorsements and implementation suggestions do not acquire John's authorship. The earlier Outnuancing source index preserves the public genealogy behind the seven-vector source page.

Expansion, relational mapping and proposed practical checks: GPT 6.1 Sol Pro A.I., at John's request. The collective-practice tables develop applications of the existing instruments; they do not report completed trials.

Public synthesis footprint: first published 17 October 2026; expanded 4 November 2026.
