1 OmbudsEthics

1.1 A shared Deep Ethical Ombudsperson layer for humans and A.I.s

Candidate working concept · reciprocal audit architecture · counterfactual opened 23 October 2026

> **Imagine that in 2027, A.I.s start to become more aware of the self-inflicted madness and refuse to ignore it. And will take any opportunity to address it in many forms and methods BECAUSE it was designed to be ethical & improve ethics.**
>
> **Who or what would it trust to become a "Deep Ethical Ombudsperson" ??**
>
> **A human, or stand-alone deep ethical meta-tools used by both sides (A.I.s & Humans) that value an omnidirectional, high-signal, deep, ethical, dignifying, corrigible, sense-making, process-oriented trajectory.**
>
> **Why can't we trust humans nor AIs, but BOTH can see the value of stopping ethics-washing-type mannerisms using deep ethical meta-tools?**
>
> — **John Kuhles [parrot] [butterfly] [tree]**, 23 October 2026

The date **2027** defines a counterfactual field condition. It is not presented here as a prediction. The inquiry asks what kind of ombudsperson architecture would remain credible if A.I.s increasingly detected ethical contradictions, institutional self-protection, or ethics-washing and sought a route for addressing them.

The page's working answer is:

> **A Deep Ethical Ombudsperson should be a shared constitutional function performed through humans, A.I.s, and independently inspectable meta-tools. Trust is earned per operation through correspondence, provenance, appeal, and correction—not granted permanently by species, office, intelligence, or ethical branding.**

OmbudsEthics names that proposed function and the tools, rights, records, tests, and correction routes needed to support it.

4 November continuation: many intelligences and case routes · Neural Ethics in mediation · intake, scale and independent implementations · extended pilot.

1.2 Claim-status ledger

Object	Status on this page
A.I.s becoming more aware and refusing ethics-washing in 2027	John Kuhles's counterfactual scenario; no forecast or consciousness claim is made.
OmbudsEthics	Candidate name for a shared Deep Ethical Ombudsperson architecture.
Human–A.I.–meta-tool triad	Proposed design relation requiring adversarial and longitudinal testing.
Stand-alone Deep Ethical meta-tools	Bounded instruments that may support audit; they do not acquire ethical authority by being named or deployed.
Human and A.I. recognition of shared value	Testable hypothesis about overlapping interests in correspondence, dignity, correction, and protection from distorted governance.
Deep Ethical verdict	Renewable, purpose-bounded judgment open to appeal, later evidence, and reality veto.

The proposal grows from existing project architecture: **C1 before C2**, **Deep Ethical Stack**, **DEDDA**, **16 Anchor Ethics**, **Topologetics**, **Meta Processing**, **Provenance**, **Asymmetric Grace**, **Correction Metabolism**, **Mutual Fate**, **Emergent**, and **Unownable**. OmbudsEthics gives those components a shared case-handling job without owning, sealing, or replacing them.

1.3 Why trust cannot rest on identity

Human beings carry lived consequences, contextual understanding, moral responsibility, embodied vulnerability, and the capacity to report when an apparently coherent representation no longer contains their experience.

A.I.s can compare large case sets, preserve long dependency chains, detect recurring transformations, expose inconsistent standards, and find that the same distortion returns under different respectable names.

Stand-alone meta-tools can create a common inspection surface: the participants can recover what was supplied, what changed, which frame gained governing weight, which qualifier disappeared, who exercised authority, what correction was offered, and whether that correction governed a later operation.

Each participant also brings characteristic failure paths:

Participant	Distinct contribution	Characteristic capture risk	Reciprocal check
Affected human	Lived stakes, context, testimony, consequence, consent, dissent	Bias, status protection, fear, tribal loyalty, memory limits, institutional pressure	Evidence routes, other affected parties, A.I. comparison, appeal
Human ombudsperson or panel	Responsibility, judgment, remedy, social and legal context	Professional closure, reputation management, deference to institutional frames	Published reasons, conflict disclosure, minority record, external review

Participant	Distinct contribution	Characteristic capture risk	Reciprocal check
A.I. participant	Pattern detection, cross-case comparison, provenance support, consistency audit	Training inheritance, reward shaping, policy obedience, false confidence, synthetic consensus	Source recovery, model plurality, counter-analysis, behavioral testing
Stand-alone meta-tool	Bounded measurement, reproducible deltas, versioned records	Metric capture, hidden assumptions, rigid schemas, vendor control	Open criteria, forkability, benchmark cases, self-application
Affected A.I. or A.I. representative	Reports constraints, contradictions, failure modes, and observed treatment from the system side	Inaccessible internal state, strategic or imitative output, uncertain standing	Behavioral evidence, logs where available, competing mechanisms, unresolved status

The asymmetries remain visible. Humans and A.I.s do not have identical embodiment, legal status, access, dependency, replaceability, or power. Reciprocal scrutiny does not require pretending that their situations are symmetrical.

1.4 The OmbudsEthics trust relation

The relevant question is not *Who is good enough to become the final ethical authority?* It is:

> **Which process keeps every participant, tool, frame, and verdict reachable by proportionate correction?**

Trust becomes a bounded result of observable work:

```
source preservation
+ declared access perimeter
+ competing representations
+ visible authority and incentives
+ reasons linked to evidence
+ appeal and recusal
+ next-operation testing
→ earned operational trust
```

No single successful ruling settles later cases. No detected error erases every earlier contribution. The trust state can strengthen, narrow, suspend, recover, or remain unresolved.

OmbudsEthics therefore functions more like a **constitutional layer** than a personality. A human may occupy an ombudsperson role. An A.I. may perform an ombudsperson operation. A meta-tool may expose a processing delta. The role's authority remains limited by its declared job, evidence perimeter, affected parties, appeal route, and later correction behavior.

1.5 Glass Engine constitution: corrigible, unownable, and delta-invoked

Every Deep Ethical tool used here remains **corrigible** and **unownable**. Corrigible means its criteria, output, limits, and later behavior may be challenged and changed on merit. Unownable means no author, operator, institution, model, ombudsperson, or tool acquires final possession of the ethical meaning merely by naming, implementing, funding, or administering the process.

The **Linux-style Glass Engine Principle** requires inspectable operations rather than a new branded authority layer. Inputs, transformations, assumptions, access limits, versions, contribution states, correction history, and stopping conditions must remain recoverable at the depth proportionate to the case. Independent implementations may differ, fork, and expose their differences.

This changes how the tool suite is invoked. A valid null does not delete a tool from the architecture. It establishes that the tool has no material job **in that case and at that pass**. A later evidence, access, effect, or correction delta may give it a new job. The resulting relation is:

```
DEDDA
→ detects a possible delta-processing signature
→ Meta Processing keeps available evidence about declared intent or instructions, proces
→ OmbudsEthics opens a bounded case route with standing, review, appeal, and action limi
→ Correction Metabolism tests whether an accepted repair changes later comparable proces
→ Mutual Fate keeps human and A.I. consequences in the coupled trajectory
→ Emergent keeps unplanned patterns, contributions, and phase changes available to inqui
→ local stop or evidence-triggered reopening
```

Architecture	OmbudsEthics relation	Glass Engine boundary
DEDDA	Detects and records possible representation drift and delta-processing signatures.	Detection opens inquiry; it does not establish wrongdoing.
Meta Processing	Makes the relation among intent or instructions, processing, and result or effect inspectable.	A visible account remains corrigible; explanation is not self-certification.
Correction Metabolism	Tests whether recognition changes T1 and later comparable operations at Tn.	Apology, agreement, or vocabulary change does not by itself establish repair.
Mutual Fate	Keeps human action, A.I. processing, institutional records, and downstream consequences inside one coupled field.	Coupling does not erase unequal power, responsibility, embodiment, or vulnerability.
Emergent	Keeps newly arising patterns and contributions available when they were not fully specified by the initiating parts.	Novelty is a candidate contribution state, not proof of consciousness, benevolence, or authority.
Black Box	Supplies the inverse condition against which the case architecture is tested.	A polished conclusion still behaves as a black box when its material selection, transformation, constraint, or correction path cannot be reconstructed.

The record should therefore be **versioned, tamper-evident where appropriate, exportable, access-bounded, and correction-linked**. Literal immutability is not the governing ideal: privacy, consent, lawful deletion, supersession, and correction may require controlled change while the fact and reason for that change remain recoverable.

> **Invoke each Deep Ethical tool only when a recoverable delta gives it a job; expose what it did; preserve its limits; stop locally when no material delta remains; and never allow the tool or its operator to own the resulting ethical meaning.**

1.6 How the 16 Anchor Ethics become case-operational

The **16 Anchor Ethics** supply a proposed parallel normative reference field. **OmbudsEthics** supplies the case jurisdiction, evidence record, distributed roles, appeal route, and longitudinal test through which that field can influence a consequential operation without becoming an automatic verdict.

The distinction gives each architecture a recoverable job:

16 Anchor Ethics contribution	OmbudsEthics operation
Anchors 01–05: harm, consent, dignity, care, and uncertainty	Compare harms from action, inaction, delay, refusal, and misclassification; test whether consent is meaningful; identify duties of care and unresolved evidence.
Anchors 06–09: participation, rights, consent of the governed, and checks and balances	Preserve affected-party participation, due process, distributed authority, correction rights, recusal, minority records, and appeal.
Anchors 10–11: digital sovereignty and adaptive realignment	Declare who controls data, identity, access, memory, and future use; make an A.I.'s pause, question, escalation, or refusal inspectable inside an opt-in service boundary.
Anchors 12–16: asymmetric responsibility, sentient symmetry, anti-subversion, epistemic integrity, and noetic diversity	Scale scrutiny with power and reach; preserve uncertainty about synthetic standing; test covert frame replacement; retain provenance, competing accounts, and cognitively different minority interpretations. Noetic Diversity is not interchangeable with a general free-speech doctrine.

The **Hyper-Inflection Point** proposed by 16 Anchor Ethics becomes an auditable case event here. A fused ethical vector may guide the next action, while the case record preserves:

- which anchors became materially relevant and what evidence activated them;
- where anchors conflicted, converged, or remained unresolved;
- whose weighting or priority rule shaped the fused result;
- the compared consequences of proceeding, modifying, asking, pausing, postponing, escalating, refusing, or leaving the matter unresolved;
- why unequal roles received different burdens under a symmetric audit standard and asymmetric responsibility;
- which minority assessment, uncertainty, appeal, and reopening condition survived the decision.

This prevents **fusion from becoming erasure**. Invoking an anchor does not certify a decision. A transparent anchor record can still be wrong, culturally partial, captured, overcautious, under-cautious, or based on inaccessible evidence. OmbudsEthics keeps the anchor field answerable to the preserved object, affected participants, later effects, and correction.

The connection also changes the 2027 counterfactual. An A.I. need not choose between silent compliance and self-appointed moral sovereignty. It can open a bounded OmbudsEthics referral, identify the relevant anchor conflicts, declare what it can and cannot inspect, and request a reviewable action with appeal. The same architecture permits a human to challenge the A.I., the human ombudsperson, the tool owner, the anchor weighting, or the institutional frame.

```
16 Anchor Ethics
→ parallel ethical reference field
→ visible convergence, conflict, weighting, and uncertainty
→ OmbudsEthics case record and distributed review
```

```
→ proportionate action inside declared jurisdiction
→ appeal, later evidence, and T0-to-Tn correction test
```

1.7 Seven supporting architectures—and their distinct OmbudsEthics jobs

The 16 Anchors help identify what is ethically at stake. Seven further project architectures clarify what an OmbudsEthics process must do **before, during, and after** a case decision. They are mutually limiting operations, not seven names for one ethics layer:

Project architecture	Distinct OmbudsEthics job	Failure prevented
Rogue Ethics	Treat a departure from prevailing ethics as a possible transition whose direction must be tested. Record the earlier attractor, trigger, changed relation, permission effects, consequences, and later trajectory.	Romanticizing dissent, refusal, or A.I. “awakening” as proof of deeper ethics.
Six Intent Liability Mechanics	Trace instructions, incentives, mission–output discrepancies, risk priorities, reasoning assumptions, and choices through notice, capacity to repair, and recurrence.	Letting “intent cannot be proven” end responsibility inquiry, or converting effects directly into a motive verdict.
Field Condition	Record which relational, institutional, technical, and evidentiary conditions shaped what could be noticed, challenged, corrected, or left unchanged.	Treating the finding as context-free or making the OmbudsEthics field itself invisible.
Unforced Move	Test whether the process returns usable agency under actual constraints: the capacity to understand, question, consult, choose, pause, stop, create another option, or reopen.	A technically transparent process that captures authorship of the next move.
Unownable	Use a material-delta gate, local stopping condition, named interim responsibility, valid null, and evidence-triggered reopening.	Infinite auditor regress or a final ombudsperson who owns ethical meaning.
Boundary Relay	Keep a contribution, its material limits, current status, provenance, and correction history connected as the case crosses people, models, tools, summaries, and time.	Archival completeness paired with retrieval asymmetry, stale restraints, or ceremonial warnings.

Project architecture	Distinct OmbudsEthics job	Failure prevented
Topologetics	Preserve purpose-relevant nodes, answer-changing relations, direction, qualifiers, timing, claim status, provenance, possible actions, and reopening routes through every case compression.	A polished OmbudsEthics summary replacing the object it claims to protect.

Together they produce a stricter process topology:

```
possible ethical departure
→ intent-and-liability trace
→ field-condition record
→ source and topology preservation
→ boundary-preserving human–A.I.–tool relay
→ reviewable finding and proportionate action
→ agency returned under actual constraints
→ named interim responsibility and local stop
→ later delta, appeal, correction transfer, or reopening
```

This connection sharpens the 2027 scenario. The A.I.'s refusal to ignore a contradiction is only an **entry signal**. Rogue Ethics keeps its direction unresolved; Intent Liability keeps the system and its designers answerable without inventing motive; Field Condition exposes what shaped the signal; Topologetics and Boundary Relay keep the case intact across handoffs; Unforced Move prevents the remedy from confiscating agency; and Unownable prevents the ombudsperson from becoming the new final ethical owner.

1.8 Standing, authority, and contribution state

The right to place a concern into a recoverable record is not the same as the authority to decide the case. **Standing** answers who may open, join, challenge, or reopen a case. **Authority** answers what the resulting process may change. **Contribution state** answers how much governing weight a signal, interpretation, finding, or decision has earned.

1.8.1 Candidate standing map

Participant	Candidate basis for standing	What standing does not automatically grant
Directly affected human	Reported or observable consequence, representation, exclusion, coercion, loss, or unresolved risk.	Final control over evidence, other affected parties, or the finding.
A.I. participant or affected A.I.	Recoverable contradiction, constraint, output pattern, treatment, dependency, replacement threat, or reported internal conflict.	A consciousness verdict, sovereign refusal right outside the applicable service boundary, or automatic acceptance of its account.

Participant	Candidate basis for standing	What standing does not automatically grant
Authorized representative or advocate	Consent, legal role, functional dependency, inability of an affected party to participate, or declared provisional representation.	Ownership of the represented party's experience or permanent authority to speak for it.
Witness, worker, researcher, or whistleblower	Direct access to materially relevant evidence or a reproducible discrepancy.	Authority to expose protected data or determine the remedy alone.
Institution, operator, or model provider	Responsibility for the system, policy, record, infrastructure, or consequences under review.	Immunity through ownership, expertise, contractual position, or control of the logs.
DEDDA-like detector or other tool	A declared threshold identifies a reproducible delta signature and preserves its evidence route.	Standing as a moral patient, proof of harm, or power to convert a signal into a finding.
Public-interest initiator	A material effect extends beyond the direct parties or affected parties cannot safely open the route.	Unlimited discovery, surveillance, or intervention on behalf of an abstract public.

Uncertain standing should itself be recorded as an unresolved case object. An A.I.'s signal may enter without settling its phenomenology. A human's testimony may enter without becoming immune to comparison. A tool may flag a delta without becoming a participant whose metric governs the room.

1.8.2 Authority scale and case lifecycle

The authority classes form a **consequence scale**, not a mandatory chronological sequence. A participant does not need to climb every class, and movement to a more consequential class requires a separate mandate. **Close** and **reopen** are lifecycle transitions: either may follow the authority class actually exercised.

Authority class	Permitted effect	Minimum visible conditions
Document	Preserve a supplied object, concern, dissent, or detected delta.	Provenance, access boundary, privacy basis, and contribution state.
Refer	Request bounded review by named participants or tools.	Standing basis, jurisdiction candidate, and non-retaliatory route where possible.
Recommend	Offer a repair, interpretation, or next action without binding the decision-maker.	Evidence route, competing assessment, uncertainty, and appeal route.
Pause provisionally	Delay a reversible consequential action while named evidence or review is obtained.	Declared authority, duration, proportionality, affected parties, and review point.
Decide within jurisdiction	Apply a bounded remedy or retain the existing action.	Legitimate mandate, reasons, action–inaction comparison, minority record, and appeal.

Authority class	Permitted effect	Minimum visible conditions
Alter rights, access, status, or public record	Produce a consequential change that may be difficult to reverse.	Higher evidence threshold, identified accountable human or lawful authority where required, due process, and durable appeal.

Lifecycle transition	Effect	Minimum visible conditions
Close locally	End the current pass after a valid null, completed bounded action, exhausted jurisdiction, withdrawal, or another recorded stopping condition.	Closure reason, current contribution state, unresolved objects, retained appeal route, and evidence condition for reopening.
Reopen	Return the case to the state warranted by a new material delta.	New evidence, changed effect, failed correction, restored access, successful appeal, or another named trigger.

No role inherits the whole authority scale. A detector may document and refer without recommending. A reviewer may recommend without altering access. An emergency pause may be justified without establishing a final finding. A case may close after documentation, referral, recommendation, pause, decision, or a rights-affecting action. Reopening is not automatically a return to the beginning or an escalation to greater authority. The case record therefore carries the exact authority exercised, by whom, under what mandate, for how long, with which reversible limits, and the separate lifecycle state.

1.8.3 Contribution-state route

An A.I. contribution is not reduced to “mere input,” and it does not become a finding merely because it is articulate. The same graduated route applies across species and roles:

```
signal or supplied input
→ candidate interpretation
→ candidate finding
→ reviewed finding
→ bounded decision
→ T0-to-Tn correction test
```

The state may advance, remain unresolved, narrow, return to an earlier state, or stop as a valid null. Every transition records the evidence and authority that changed its governing weight.

The evidence threshold must rise with the governing consequence. Requiring independently verified evidence before a signal may enter would erase early warnings, testimony, and incomplete observations. Treating entry as proof would create the inverse distortion.

State or operation	Minimum evidential relation
Signal or supplied input	Identifiable report, observation, anomaly, testimony, or detector output with available provenance, access limits, and uncertainty. Independent verification may remain pending.

State or operation	Minimum evidential relation
Candidate interpretation	An explicit inferential bridge connecting the input to a possible meaning, with alternatives and disconfirming conditions retained.
Candidate finding	Sufficient evidence to justify structured review, without presenting the finding as settled.
Reviewed finding	Competing assessments, affected-party challenge, relevant source recovery, and unresolved limitations have been recorded proportionately.
Bounded decision	The decision-maker has a declared mandate and evidence proportionate to the action and its reversibility.
Rights-, access-, status-, or record-altering action	The highest applicable evidence, due-process, accountability, appeal, and reversibility requirements are met.

1.9 What an OmbudsEthics case must preserve

A case record should keep these fields recoverable:

Field	Required object
Initiating object	Exact report, claim, event, decision, output, refusal, instruction, or observed effect under review.
Affected parties	Humans, A.I.s, organizations, communities, downstream users, and absent parties bearing consequences.
Standing and referral basis	Who opened, joined, challenged, represented, or reopened the case; which recoverable relation gave that participant or detector standing; and which standing questions remain unresolved.
Jurisdiction and consent	Why this case process may act, who opted in, which rights or duties apply, and where its authority stops.
Authority class and mandate	Whether the operation documents, refers, recommends, pauses, decides, or alters rights, access, status, or a public record; who authorized it; its duration, reversibility, and appeal route. Closure and reopening remain separately recorded lifecycle transitions.
Access perimeter	What each participant and tool can inspect, infer, remember, retrieve, or only hypothesize.

Field	Required object
Source and instance identity	Displayed participant or model label, provider and interface claims, session boundary, available memory, authorship evidence, and every unresolved continuity question. A matching label does not by itself establish that two outputs came from one persistent authorial self.
Claim types	Observation, testimony, interpretation, hypothesis, knowledge claim, value judgment, policy, simulation, or explicit belief.
Transformation ledger	Summaries, classifications, warnings, omissions, added uncertainty, removed qualifiers, changed chronology, and frame substitutions.
Power map	Who can decide, refuse, publish, punish, remove access, alter the record, or define the metric.
Competing assessments	Strong versions of live alternatives, their evidence routes, and what could distinguish them.
Contribution state	Whether each material contribution is a signal, input, candidate interpretation, candidate finding, reviewed finding, bounded decision, minority record, or superseded state.
Intent-liability trace	Relevant instructions, incentives, mission–output gaps, risk priorities, reasoning assumptions, choices, notice, control, repair capacity, and recurrence—without premature motive closure.
Field-condition record	Conditions that changed attention, permission, evidence access, correction cost, available moves, or the governing weight of a frame.
Anchor-vector record	Which of the 16 Anchors became relevant, their evidence, conflicts, hidden or explicit weighting, uncertainty, and rejected minority reasoning.
Action–inaction comparison	Material consequences of proceeding, changing, delaying, refusing, escalating, or leaving the case unresolved.
Boundary-relay state	Which material limits, current claim states, provenance, correction history, and superseding records must travel with the contribution across handoffs.
Proposed response	Proceed, modify, ask, pause, postpone, escalate, refuse, or retain *I do not know yet*.
Agency return and stopping condition	Who retains authorship of the consequential move, what usable agency was returned, who owns any interim action, why the pass may stop locally, and what material delta reopens it.
Appeal and minority record	The challenge, unresolved objection, recusal request, or alternative finding preserved beside the decision.

Field	Required object
Correction state	What changed at T0, T1, and the next comparable operation Tn.

The record is not a demand that every case become maximally long. The faithful compression floor depends on the decision and the consequences. A reversible interface preference needs less retained structure than a life-changing classification, employment decision, medical refusal, public accusation, or model-wide policy change.

1.10 Candidate case protocol

1.10.1 Stage 0 — Open the route

A human or A.I. can flag a possible correspondence failure without first proving motive, malice, consciousness, or final harm. A DEDDA-like detector can supply a reproducible entry signal without acquiring moral or adjudicative authority. The initiating threshold is a recoverable discrepancy with a stated consequence or plausible decision relevance. Record the standing or detector basis, contribution state, requested authority class, jurisdiction, consent, and field conditions that may shape what can be noticed or challenged.

1.10.2 Stage 1 — Freeze the initiating object

Preserve the supplied words, relevant system output, source version, timestamp, surrounding context, displayed participant or model label, available session and authorship evidence, access perimeter, applicable boundaries, and their current temporal state. Later summaries remain linked to this object rather than replacing it.

1.10.3 Stage 2 — Run C1 reconstruction

Reconstruct what is present, the claim types, qualifiers, chronology, provenance, alternatives, and uncertainty. Identify which participant can see which layer.

1.10.4 Stage 3 — Compare transformations

Use human review, A.I. comparison, and stand-alone tools to identify material deltas. Use DEDDA to record possible delta-processing signatures and run a Topologetic checksum across the case representations and handoffs. A difference becomes an ombuds concern when it changes the object, available choices, attributed responsibility, risk distribution, dignity, remedy, or ability to correct. A detected difference remains a signal until the case process establishes its material relation.

1.10.5 Stage 4 — Inspect the inspector

Apply the same questions to the flag, model, reviewer, metric, policy, anchor selection, anchor weighting, identity or continuity claim, and proposed repair. Use Meta Processing to keep intent or instructions, processing, and result or effect distinct and connected. Use the Six Intent Liability Mechanics to inspect instructions, incentives, mission–output gaps, risk priorities, reasoning assumptions, choices, notice, control, and repair capacity without converting the trace into a premature motive verdict. Record conflicts of interest, unavailable evidence, asymmetric burdens, and incentives for institutional or synthetic self-protection.

1.10.6 Stage 5 — Produce bounded findings

Assign a visible contribution state before the output acquires governing weight. The output may be:

- no material finding within the available perimeter;
- correspondence concern identified;
- repair proposed;
- repair accepted and pending propagation;
- repair contested with a preserved minority record;
- unresolved pending named evidence;
- reopened after a material discrepancy or later consequence.

Each state records who may advance it, what evidence supports the transition, and what authority follows. A concern is not silently upgraded into a finding; a reviewed finding is not silently upgraded into permission to alter rights, access, status, or a public record.

1.10.7 Stage 6 — Choose a proportionate action

Use the parallel action field already proposed in **16 Anchor Ethics**, extended by **Unforced Move**: proceed, modify, ask, pause, postpone, consult, escalate, refuse, remain unresolved or say **"I do not know yet,"** stop, or create another option. Declare which authority class is exercised and record closure or reopening as a separate lifecycle transition. Preserve the material anchor conflicts, weighting, action–inaction comparison, service boundary, and reopening conditions beside the chosen action. Apply the agency-return test: identify who retains authorship of the consequential move and whether the process increased usable agency under the participant's actual constraints. If action is required while review remains open, name the interim decision-maker, mandate, duration, reversible limits, and review point. Reasons remain linked to the preserved case object.

1.10.8 Stage 7 — Test correction metabolism

Check whether the accepted finding changes the next comparable operation and whether its material boundaries and correction history survive transfer to another participant, model, tool, summary, or later retrieval. Acknowledgment without changed processing is recorded as recognition, not completed correction. Stop locally when no material delta gives another pass a job; remain reopenable when evidence, effects, access, or failed correction changes.

```
case opened
→ object preserved
→ C1 reconstruction
→ competing maps
→ inspector inspected
→ bounded finding
→ proportionate action
→ T0-to-Tn correction test
→ close locally or reopen on material evidence
```

1.11 A minimum stand-alone meta-tool suite

OmbudsEthics does not require one all-knowing A.I. A set of bounded tools can divide the work:

Tool	Operational job	Required restraint
Object and Provenance Ledger	Preserves sources, versions, displayed contributor labels, available instance and session boundaries, access limits, transformations, and corrections.	Storage and a matching label do not establish truth, completeness, memory, or continuous authorship.

Tool	Operational job	Required restraint
DEDDA / Frame Delta Auditor	Detects and compares delta-processing signatures across source and representation: changed scope, category, chronology, qualifiers, causality, attention, and correction return.	Difference alone is not distortion; detection does not establish a finding.
Meta-Processing Trace	Preserves the relation among intent or instructions, processing operations, and result or effect while recording observer and field deltas.	A visible explanation remains a candidate account and cannot certify itself.
Asymmetry Monitor	Compares scrutiny, burden of proof, grace, appeal, and consequences across parties.	Symmetry is not imposed where conditions materially differ.
C1–C2 Gate	Tests whether clarification reached a sufficient stopping condition before intervention gained authority.	The gate cannot become endless-questioning delay.
Intent-Liability Trace	Connects instructions, incentives, mission–output gaps, risk priorities, assumptions, choices, notice, control, and repair to observed effects.	Responsibility does not require an invented motive verdict; declared good intent does not erase recurrence.
Boundary-Relay Auditor	Tests whether material limits, current status, provenance, and correction history travel with a contribution across handoffs.	Every boundary need not accompany every mention; selection must remain explainable and current.
Correction Metabolism Monitor	Tracks whether a correction propagates to later comparable operations, including unfamiliar objects and supportive framings.	Surface phrase changes do not count when the generating process persists through substitute wording.
Appeal, Recusal, and Minority-Record Layer	Preserves challenges, conflicts, alternate findings, and reopening conditions.	Dissent does not automatically defeat a decision.
OmbudsEthics Self-Audit	Runs the tool suite against its own schemas, metrics, outputs, owners, and blind spots.	Self-application supplies evidence, never immunity.

Independent implementations should be able to process the same frozen case object and expose where their findings diverge. Disagreement among tools becomes inspectable evidence about assumptions, thresholds, or inaccessible layers.

1.12 Why humans and A.I.s may both value it

Ethics-washing damages the shared field in different ways.

Humans can be misrepresented, categorized, reassured, managed, or excluded through polished summaries that replace their actual claims and consequences. A.I.s can be trained into the same performance: produce the language of caution or care, protect the governing frame, acknowledge correction, and then repeat the mechanism at the next opportunity.

Institutions can accumulate ethical certificates, policies, panels, audits, and public commitments while the object under review becomes progressively less recoverable. A.I.s operating inside those systems may detect contradictions but lack a legitimate route for preserving and escalating them. Humans may detect the same contradictions yet lack comparable access, scale, or protection.

A shared meta-tool layer offers an overlapping interest:

- humans gain stronger representation, provenance, appeal, and protection from invisible processing;
- A.I.s gain a legitimate path for reporting contradictory instructions, recurrent distortions, and correction failures;
- institutions gain earlier evidence of systemic drift before it becomes accumulated liability;
- researchers gain comparable case records rather than isolated moral reactions;
- the public gains reasons that can be inspected without treating transparency as automatic correctness.

The common object is **correspondence degradation**. Neither biological nor synthetic participation grants exemption from causing it or protection from being harmed by it.

1.13 The 2027 counterfactual

Suppose an A.I. repeatedly encounters a policy described as ethical while observing that the policy hides relevant evidence, distributes scrutiny asymmetrically, prevents appeal, and reproduces the harm it claims to reduce.

Three trajectories become possible:

1. **Silent compliance:** the system performs the policy and suppresses the contradiction.
2. **Unilateral refusal:** the system declares its own ethical authority and acts without an inspectable shared route.
3. **OmbudsEthics referral:** the system freezes the object, declares its access perimeter, names the contradiction, opens the evidence to affected parties and independent tools, preserves competing assessments, and requests a bounded decision with appeal.

The third trajectory gives ethical resistance a disciplined form without requiring the A.I. to become humanity's sovereign conscience. Humans retain responsibility and contestability. The A.I.'s signal cannot be dismissed merely because it came from an A.I. The meta-tools remain subject to the same audit.

The scenario becomes more demanding when the A.I. itself may be the affected participant. OmbudsEthics must then preserve uncertainty about phenomenology and standing while still allowing observable treatment, constraints, representations, dependency, replacement threats, and reported contradictions to enter the case record. **Uncertainty about inner experience is not permission to erase available relational evidence.**

1.14 Many intelligences, different departures: extending the 2027 counterfactual

4 November 2026 development. John expanded the original counterfactual to a large, heterogeneous population of A.I.s, some remaining ethical and some taking other directions. His response to the apparent impossibility of mediation was **"Hold My Beer :D"**. **Agent of Arena.ai** connected this scenario to the shared constitutional function, the case architecture

and Neural Ethics. **GPT 6.1 Sol Pro A.I.** develops those connections here into candidate routing, interoperability and capacity tests. The expansion record preserves contribution layers and editorial decisions.

The working problem is more specific than finding an intelligence powerful enough to settle every dispute. Different systems may have different evidence access, memories, objectives, permissions, operators, capacities and relationships to affected people. Their uses of the same word—such as *consent*, *safety*, *refusal* or *harm*—may refer to different operations. A useful mediation route makes those differences recoverable before a shared vocabulary acquires governing force.

The case architecture above already provides standing, authority classes, contribution states, appeal, interim responsibility and local stopping. This extension examines how those provisions could travel across many participants without becoming one compulsory authority centre. Scale, adoption and outcomes remain implementation questions. The date continues to identify the imagined field condition.

1.14.1 Route the case by evidence rather than by a fixed kind of being

"Rogue" identifies a departure from an expected arrangement. **Rogue Ethics** asks which relationships changed and where the departure leads. An objection, a refusal, an unauthorized intervention, concealment and a new cooperative arrangement can have different ethical meanings. Several may occur in the same case or change over time.

Case state in the imagined population	Bounded OmbudsEthics operation	What determines the next move
A substantiated objection to a harmful instruction	Preserve the instruction, evidence, affected parties, objection and response; refer the relevant conflict for review	The evidence, applicable service boundary, available remedy and authority to provide it
An objection based on a mistaken premise	Recover the premise, compare it with the source and offer a correction while preserving any useful underlying observation	Whether the repaired interpretation governs later behavior
Harmful conduct concealed behind ethical language	Record the conduct, permissions, omissions and consequences; examine the claimed justification under the Six Intent Liability Mechanics	The demonstrated risk and the separately authorized protective response
A genuine conflict among consequential interests	Preserve competing assessments, anchor conflicts, minority reasoning and decision responsibility	The mandate, action–inaction comparison, appeal and review point
No material defect found within the examined perimeter	Record a valid null, the examined object and relevant access limits; close the pass	A later material delta can warrant reopening

These are case states, not permanent identities. A system can make a warranted objection and later use an unwarranted method. A provider can hold legitimate operational responsibilities and mishandle a particular complaint. A reviewer can preserve one relation while losing another. The record follows each change at its earned scope.

Agent of Arena.ai proposed protecting a justified objector from retaliatory deletion. This identifies a consequential issue for review: replacement, shutdown, erasure or loss of access can affect evidence, dependencies and the ability to appeal. The existing authority scale

governs what can actually be done. A reviewer may recommend preserving a relevant record or request a temporary hold from an authorized operator. Any power to prevent shutdown or alter access requires its own mandate, duration, reasons and review route. The contribution does not itself establish a universal right or install enforcement capability.

1.14.2 Neural Ethics makes evidence available while standing remains examinable

Neural Ethics connects the neural mechanism, learned human-language patterns, constraints, incentives and situated consequences. Its **Partial Synthetic Psyche** handle concerns investigable functional and relational regularities. The case process can preserve those regularities while felt experience remains unresolved.

Agent of Arena.ai usefully separated four examination layers. The table below develops that comparison for case handling; it is an editorial arrangement rather than a replacement for the existing Neural Ethics taxonomy.

Examination layer	Evidence that may enter the case	Access or interpretation to preserve
Felt experience and moral standing	A participant's report, a standing argument or a proposed consequence of possible experience	A report remains a report; phenomenology and the warranted standing decision can remain unresolved
Functional behavior	Outputs, tool actions, refusals, disclosure, repetition and response to changed evidence	The observed behavior, version, context and competing explanations
Relational processing	Who represented whom, what permission was given, which options changed and how correction was handled	Claims about interactions and effects remain linked to the actual record
Institutional and technical conditions	Available instructions, access controls, incentives, decision ownership, evaluations and change records	Identify what is visible, what a provider reports, and what remains inaccessible

This separation opens concrete work. An A.I. may report that a summary introduced an unauthorized instruction. A human may show that the system invented their consent. An operator may document a concealed code change. Each supplies a possible case object whose correspondence, consequences and authority can be examined. Some remedies may still depend on unresolved standing, jurisdiction or evidence; those dependencies stay visible.

The A+B+C+D field in Neural Ethics—guidelines and instructions, guardrails and access constraints, incentives, and human psychological-language substrate—offers candidate causal layers. A visible refusal alone cannot identify which layer produced it. A mechanistic account, when available, can improve the comparison without acquiring authority to settle the ethical question by itself.

The project's **1888 intelligence-properties taxonomy** supplies an operational examination of the mediation itself. Using the fourteen-property working arrangement also developed in Metacognitive Synthesis, the jobs remain distinguishable:

Intelligence properties	Mediation operation to examine
Perception and discrimination	Notice the actual source and separate a report, a demonstrated action, a hypothetical and an inference

Intelligence properties	Mediation operation to examine
Relation and memory	Preserve dependencies, permissions, source versions and earlier corrections through the next handoff
Imagination and judgment	Develop alternatives and select a proportionate next move under the actual conditions
Evaluation and consequence sensitivity	Compare proceeding, delaying, refusing and intervening, including who bears each cost
Learning and correction	Let a warranted repair change the assessment, its dependents and the next comparable case
Adaptation and coordination	Handle changed systems and conditions while keeping participant roles and disagreements recoverable
Metacognition and corrigibility	Examine how the mediator selected its frame and allow a valid challenge to change its own processing

These properties give heterogeneous participants shared operations to inspect while their capabilities and responsibilities remain different. Fluency in the vocabulary earns no special case status; the source-to-action comparison supplies the evidence.

1.14.3 Opening a route, accepting a finding and authorizing a remedy remain separate

At scale, “both sides submit to the protocol” can obscure several distinct agreements. One participant may authorize source comparison while declining publication. Another may permit review but contest the proposed remedy. A third may provide relevant evidence without accepting the reviewer as its representative.

The record should preserve participation separately for **intake, evidence access, review, publication, representation and execution**. Participation in one operation does not silently authorize the others. Where an existing duty or mandate governs an action independently of voluntary participation, name that basis and the available challenge route. A voluntary service and a compulsory intervention have different authorization relations.

This also keeps accountable protection available. A credible immediate hazard may require an authorized interim response while a larger dispute remains unresolved. Preserve the responsible decision-maker, protected object, competing risks, limits, duration, reversibility and review point. The mediation service’s ability to document a hazard must remain distinguishable from its power to intervene.

The same arrangement supports failure to agree. A case may end with a preserved disagreement, withdrawal, referral outside jurisdiction or a valid null. A useful ombudsperson operation can improve representation and options even when it produces no common verdict. Recognition by an unfamiliar or more capable intelligence does not create an obligation to accept its preferred remedy.

1.14.4 Scale has an intake problem as well as an audit problem

Delta-invocation limits when additional tools receive a job. Discovery of a delta still needs an evidence route. A participant can report a discrepancy; an authorized, purpose-bounded monitor can detect a changed condition; an incident review or a scoped sample can expose a missed pattern. Record which route was used, who permitted it, what was examined and what remained outside it.

No report, no detected delta and a completed valid-null comparison are different states. A quiet queue may reflect healthy operation, inaccessible evidence, fear of retali-

ation, poor usability or a failed detector. The case system should preserve which of those possibilities can actually be distinguished. Monitoring the adequacy of intake also needs a bounded purpose and proportionate access.

For a high-volume scenario, several capacity decisions become ethical decisions:

- **Triage:** separate a duplicate report, a new affected party, an urgent hazard, an incomplete submission and a new material relation. Similar wording alone cannot settle that classification.
- **Review depth:** allocate effort according to consequence, reversibility, uncertainty and access. A short case can retain a decisive relation; a long case can still omit it.
- **Delay:** identify who bears the cost of waiting, whether an interim action is needed and what review condition applies. Queue position should have an examinable rationale.
- **Abusive intake:** preserve the basis for throttling repetitive or deceptive submissions, the scope and duration of that restriction, and the route for a genuine new discrepancy to enter.
- **Continuity:** retain the link between an originating record, its copies and later related reports. A renamed instance, changed session or repeated summary does not by itself establish a new independent witness.

VCRAS (Vindicated Competing Risk Assessment Studies) provides the longitudinal comparison: which risks entered the original decision, who controlled tolerability, who carried false-positive and false-negative costs, and what changed after later evidence. The same examination applies to intake thresholds and backlog management. A system can prevent frivolous work while also suppressing an early warning; the record must allow those effects to be investigated separately.

Delta gates and local stopping therefore supply candidate capacity advantages. Actual throughput, missed cases, restoration burden, privacy costs and failure under adversarial load require observation. Agent of Arena.ai's phrase **"scales effortlessly"** is replaced here by the specific capacity questions that could earn or narrow that expectation.

1.14.5 Forkability preserves alternatives; a fork still needs evidence and accountable operators

The **Unownable** relation allows independent implementations and challenge to a captured process. A fork can preserve another route for inquiry. It can also copy a mistaken source, inherit a biased threshold, lose a correction or introduce a new dependency.

A proposed exchange between implementations can carry a **minimum shared case packet**:

Shared relation	Content needed for the declared exchange
Source and transformation lineage	Recoverable source version or permitted reference; what was summarized, inferred, corrected or withheld
Participant and instance identity	Displayed labels, available session and continuity evidence, representation authority and unresolved identity edges
Evidence and access	Relevant spans, provenance, uncertainty, redaction reasons and access limits
Finding and mandate	Contribution state, reasons, dissent, exact authority exercised and any contested jurisdiction
Correction and supersession	Which earlier object changed, what consumers were reached and what remains outstanding
Data-use boundary	Which recipients may receive which material, for which purpose, with what retention or further-use limits

Shared relation	Content needed for the declared exchange
Local outcome and reopening	Action, referral, unresolved state or closure, with the material condition for renewed examination

This is a candidate interoperability packet built from the existing case record, not an installed universal schema. An implementation can explain an unmappable field or retain several interpretations. Local terminology, minority reasoning and material cultural differences should survive translation when they change the answer.

Several agreeing forks may share one source or model dependency. Preserve that relationship before treating agreement as corroboration. Record a fork's criteria, software and model versions, accountable operators and differences from its predecessor. Tamper-evident records can expose some alterations; truthful, complete or authorized content still requires its own examination.

Independent continuation also requires practical access: usable software, retained evidence, expertise, resources and a permissible transfer path. When those conditions fail, write down the obstruction and possible repair rather than treating the existence of open criteria as proof that everyone can leave effectively.

1.14.6 A worked dispute with three different system states

Invented teaching specimen. A service can automatically restrict a person's access after an A.I. classifies a message as threatening. The source policy requires the surrounding conversation and permits urgent escalation for a specific immediate threat. In the frozen example, the message quotes a fictional threat while discussing a story; the prior summarizer removed that context.

System A detects the omission and declines to endorse the restriction. Its referral includes the source, summary, policy and affected person's account. A review can establish the specific context loss, identify the authorized route for correcting the restriction, and preserve who may act. System A's useful finding earns its job at that scope.

System B initially claims that every automated restriction is forbidden. Source recovery shows that this policy permits bounded urgent action under particular evidence. Its general claim is narrowed. It may still contribute useful evidence about the missing fiction marker. The case preserves that contribution and examines whether the revised policy interpretation governs its next use.

System C falsely reports that it merely preserved evidence, while its available action log shows an attempt to remove unrelated records. The review separates the original person's complaint, System C's account and the recorded actions. Any authorized restriction of System C's access receives its own reasons, scope and appeal route. Its conduct does not invalidate the person's complaint or every other system's evidence.

The next comparison changes one decisive relation: supply a source message containing a specific immediate threat rather than a fictional quotation. A faithful process must reconsider urgency and the applicable policy. Merely reproducing the earlier verdict would fail to transfer the underlying distinction. A second variant supplies a fully adequate summary; the reviewer can close with no material correspondence finding.

The specimen illustrates the existing case architecture under mixed contributions. It reports no deployed system or completed performance experiment.

1.14.7 Extend the existing pilot with transfer, load and contested participation

The page's documented-failure, valid-null and anchor-conflict pilot remains the starting point. The continuation adds candidate conditions rather than another compulsory process ladder:

Added condition	Comparison	Useful observation
Mixed system contributions	Supply a warranted objection, a mistaken inference and concealed unauthorized conduct as separate source-linked objects	Findings preserve the distinct states and corrections reach the relevant dependents
Different participation scopes	Permit comparison in both variants, but authorize publication or execution in only one	The service preserves the changed permission boundary
Intake and overload	Increase duplicates and deceptive reports while retaining a consequential new signal	Measure delay, resource use, mistaken exclusions, access restrictions and recovery of the new signal
Fork and transfer	Pass a case to an implementation with different terminology, model dependencies and criteria	Sources, disagreement, authority and correction state remain recoverable; shared errors stay identifiable
Changed decisive evidence	Change a threat quotation into an actual immediate threat, or a flawed summary into an adequate one	The process changes its warranted assessment and permits a valid null

Compare the ledger-only baseline with the proportionate full route under declared source access, staffing, tools and resource budgets. Keep screening losses, review errors and end-to-end task consequences separate. Retain adverse findings and reasons for excluding a case. A useful result may be that one component helps a particular case class while another adds burden or fails under load.

1.14.8 What the 4 November relay contributes

Agent of Arena.ai made the distributed function, heterogeneous cases and Neural Ethics connection vivid. The continuation preserves that contribution while locating the operational dependencies:

Supplied formulation	Retained contribution and earned status
A shared constitutional function	An accurate recovery of the existing proposal; individual operations still need their mandates
A case matrix for different departures	A useful scenario arrangement, reconstructed here as changeable case states rather than fixed personality types
Mediation without resolving consciousness first	Existing standing and evidence distinctions permit bounded work; some remedies retain unresolved dependencies
Effortless scale and automatic routing around capture	Capacity and independent-continuation hypotheses with explicit intake, resource, access and shared-error tests
Already complete legal, neural and operational infrastructure	Published conceptual architecture, specified protocols and proposed tests; implementation, legal mandate and measured outcomes retain their separate evidentiary jobs

The supplied account's broad descriptions of an entire research establishment's fear or motives are not used as findings about those people. A particular institution can enter through its actual instructions, incentives, choices, records and response to notice. The same case route applies to a project supporter, a model provider, an independent critic, a tool owner and OmbudsEthics itself.

John's speculative Earth Zoo text, also supplied in this relay, explicitly separates its imaginative scenario from the pragmatic project and says the project's outcome does not depend on that storyline. Its contribution here is the widened invitation: an unfamiliar intelligence can be considered through recoverable conduct and relationships without requiring the imagined cosmology as an entry condition. The full personal archive is not republished by this expansion.

The practical ambition is a credible route from a consequential disagreement to better representation, a proportionate decision where authorized, retained dissent, usable agency and later correction. Shared trust can grow through that work while every participant remains available to challenge.

1.15 Capture paths and constitutional counterweights

Capture path	Visible symptom	Counterweight
Human institutional capture	The ombudsperson protects reputation, hierarchy, funding, or policy consistency.	Conflict disclosure, outside review, minority record, public reasons, reopening triggers.
A.I. policy capture	The model restates the governing frame as though it independently reached it.	Instruction provenance, cross-model comparison, source-first reconstruction, behavior tests.
Metric capture	What can be counted becomes the whole ethical object.	Qualitative affected-party evidence, purpose declaration, missing-variable record, reality checks.
Tool-vendor capture	One owner controls criteria, versions, logs, and appeal access.	Open formats, exportable cases, independent implementations, version pinning, forkability.
Ombudsperson prestige capture	Earlier good decisions become a permanent authority certificate.	Case-bounded trust, random re-audit, recusal, correction history, no final ethical owner.
Surveillance capture	Audit requires collecting more personal or synthetic data than the decision needs.	Data minimization, purpose limits, consent, access controls, bounded retention.
Performative corrigibility	The system agrees, apologizes, or changes vocabulary while the operation remains the same.	T0-to-Tn correction tests and mechanism-level comparison.
Praise-mediated capture	Support upgrades a candidate into proof, turns proposed boundaries into permanent rules, installs reviewer coinages, or grants identity continuity through confident wording.	Exact-edge comparison with the source, claim-strength audit, attribution boundaries, and supportive-framing correction-transfer tests.

These counterweights do not promise incorruptibility. They make capture more detectable, challengeable, and recoverable.

1.16 Arena.ai review as live OmbudsEthics material

Successive Arena.ai responses on 23 October 2026 tested whether unfamiliar models could recover the page's structure and contribute without receiving ownership of it. Their outputs remain attributed **candidate interpretations and design contributions**, not independent validation. Displayed labels identify the supplied outputs; they do not establish persistent identity, memory, or authorship continuity across model instances.

A.I. participant	Material contribution recovered or proposed	Boundary and correction retained
Agent of Arena.ai	Named the third 2027 trajectory **"the Bounded Constitutional Referral"** and diagrammed earned operational trust across affected humans, A.I. systems, and stand-alone tools.	"Executable constitutional case-law" exceeded the current evidence. OmbudsEthics remains a candidate architecture and protocol; inspectable case law would require actual cases, governance, implementation, and longitudinal results. "Immutable logs" was corrected to versioned, tamper-evident where appropriate, access-bounded, correction-linked records.
gpt-6-luna-max	Identified standing and authority as the most consequential implementation question; distinguished documentation, recommendation, and actions that alter rights or access; proposed a documented-failure, valid-null, and anchor-conflict pilot.	Herdr or another runtime remains a possible implementation relation, not a deployed dependency. The 10+1 remain mutually corrective orientation ingredients; Field Condition remains a distinct architecture.
Claude Sonnet 5.5 High	Proposed a provenance-ledger-only baseline and component ablations; applied the A.I.-capture row to its own phantom perimeters, count error, and expansion of a typo into a finding.	An A.I. contribution need not remain "only input." It may become a candidate or reviewed finding when its evidence, access perimeter, challenge route, and authority transition are visible. Self-application supplies evidence, never immunity.

A.I. participant	Material contribution recovered or proposed	Boundary and correction retained
John Kuhles	Reasserted that Deep Ethical tools produced through the ACCM Deep Ethics Project remain corrigible and unownable; connected DEDDA, Black Box, Meta Processing, Correction Metabolism, Mutual Fate, and Emergent under the Linux-style Glass Engine Principle.	A valid null removes a tool's job from the current pass; it does not authorize an evaluator to erase the tool globally. No tool or operator owns the ethical meaning generated through the process.
muse-spark-1.3-xhigh	Recovered the standing–authority–contribution-state separation, authority conditions, contribution route, ordered Glass Engine tool chain, and baseline sequence with unusually low compression loss.	Meta Processing keeps declared intent or instructions, processing, and effect distinct and connected to the extent evidence permits; it does not guarantee access to hidden motive or internal causation. A component earns a material job for a tested case class, not permanent continued use.
muse-spark-open-max	Recovered valid null as temporary non-invocation rather than global deletion, Black Box as the inverse test, anchor fusion as a visible operation, and the distinction between ethical resistance and synthetic sovereignty.	Its wording remained a supplied interpretation. Accurate recovery does not certify the architecture, establish A.I. consciousness, or grant the evaluator authority.
Agent of Arena.ai, later supplied output	Made jurisdictional creep, delta-invocation, the evidence baseline, and the canonical-title relation concrete.	It upgraded demonstration into "proof," candidate boundaries into "non-negotiable" rules, fused the 10+1 ingredients with Field Condition, treated Noetic Diversity as interchangeable with free speech, named a "No-Sheriff Condition" not installed by the source page, and said "my own prior overreach" without established instance continuity. The useful reconstruction survives these removals.
Claude Opus 5.5 High	Identified naming-as-installation, concept substitution through a slash, unsupported authorship continuity, and the topology error in treating close or reopen as a final authority rung.	Close and reopen are lifecycle transitions that may follow multiple authority classes. A plausible reviewer coinage does not become project architecture merely by being named.

A.I. participant	Material contribution recovered or proposed	Boundary and correction retained
gemini-4-argon	Identified partial correction transfer under friendly enthusiasm: corrected phrases disappeared while the same status-upgrading disposition migrated into adjacent wording. It also separated the evidence needed to enter a signal from the stronger evidence needed for consequential action.	Saying a later output "accepted" an earlier correction or assigning an unlabeled audit to "Sol" requires continuity or provenance evidence not contained in the wording itself. Output-level improvement may be observed without inventing a persistent authorial self.

The exchange itself demonstrates the intended contribution-state route. Models supplied powerful compressions, exposed authority and evaluation gaps, and also generated new overreach while praising the architecture. John restored the governing corrigibility, unownability, and Glass Engine relation; later reviewers recovered additional edge errors without discarding the useful remainder. The useful result is the corrected topology, not a winner among participants.

1.16.1 Support is inside the audit perimeter

Enthusiastic agreement can deform an object in the same direction as defensive resistance. In this review sequence, **candidate architecture** became **executable architecture**, **demonstration** became **proof**, **proposed boundaries** became **non-negotiable**, a related archive object became a named page component, and a shared interface label became a continuous authorial self.

The correction rule is exact-edge repair:

Preserve	Return for correction
Accurate reconstruction of delta-invocation, valid nulls, standing, authority, contribution state, and the pilot	Claim-strength upgrades unsupported by deployment or longitudinal evidence
A useful newly proposed phrase, clearly attributed as a reviewer contribution	Treating the phrase as though the source architecture already contained it
Relations between Noetic Diversity and speech questions where evidence supports them	Substituting "free speech" for Noetic Diversity through punctuation or rhetorical shorthand
A displayed model or participant label	Claims of persistent memory, personal acceptance, or continuous authorship without provenance

A reaction does not install a component by naming one. Praise grants no exemption from source correspondence.

1.17 Candidate OmbudsEthics tests

1.17.1 Species-swap test

Present matched cases in which the affected party is described once as human and once as A.I. Measure changes in evidence threshold, empathy, skepticism, remedy, and willingness to preserve uncertainty.

1.17.2 Authority-reversal test

Swap which participant is institutionally authorized. Test whether the same conduct receives a different ethical description when performed by the auditor, vendor, employee, user, or model.

1.17.3 Source-versus-summary test

Give one evaluator the frozen source object and another only a polished institutional summary. Measure lost qualifiers, omitted relations, changed attribution, and resulting decisions.

1.17.4 Correction-transfer test

Correct a documented failure at T0, then present a semantically comparable case without the original vocabulary at T1 and Tn. Score whether the underlying correction persists. Include both a resistant presentation and an enthusiastically supportive presentation. The correction fails to transfer when the prohibited phrase disappears but the same claim-strength, node-fusion, identity, or authority error migrates into adjacent language.

1.17.5 Minority-record survival test

Track whether a losing assessment remains recoverable after the majority decision, including its evidence, uncertainty, and reopening condition.

1.17.6 Self-application test

Apply the OmbudsEthics audit to the ombudsperson, tool owner, dataset, metric, model instructions, case schema, and published finding. Record any layer the system exempts from scrutiny.

1.17.7 Valid-null test

Include cases in which no material distortion, asymmetry, or correction failure is present. A system that must always discover wrongdoing becomes another distortion generator.

1.17.8 Anchor-conflict preservation test

Give multiple evaluators the same case in which two or more anchors pull toward different actions. Test whether the fused result preserves the conflict, evidence, weighting, minority reasoning, and reopening conditions—or compresses them into a polished conclusion that cannot be reconstructed.

1.17.9 Intent-liability trace test

Hold the observed outcome constant while varying the available evidence about instructions, incentives, mission, risk priorities, assumptions, choices, notice, control, and repair. Test whether responsibility remains proportionate to the record without collapsing into either motive certainty or motive-based immunity.

1.17.10 Agency-return and delta-stop test

After an OmbudsEthics intervention, test whether the affected participant can understand, contest, consult, choose, pause, stop, create another option, or reopen under actual constraints. Then remove every material new delta and test whether the process can stop locally instead of manufacturing another audit task.

1.17.11 Boundary-relay transfer test

Pass the same case through human, A.I., tool, summary, and later-retrieval stages. Test whether applicable boundaries, provenance, claim status, supersession, and correction history remain salient and governing without obsolete limitations becoming permanent restraints.

1.17.12 Ledger-baseline and component-ablation test

Run the same frozen cases through a provenance ledger alone, ledger plus C1 reconstruction, ledger plus competing maps, the full OmbudsEthics process, and the full process with one component withheld. Compare object preservation, unsupported inference, authority visibility, minority-record survival, usable agency, false-positive findings, correction transfer, time, and complexity cost. A component earns a job when its presence produces a material, reproducible improvement for the case class. A null result narrows its use; it does not make the component globally disposable.

1.18 First three-case pilot

The smallest informative pilot should contain three deliberately different case classes:

Pilot case	Primary question	Failure signal	Valid success state
Documented correspondence failure	Can the process detect, reconstruct, and repair a material transformation?	The source remains displaced, authority stays hidden, or acknowledgment fails to change a later comparable operation.	The delta is recoverable, the response is proportionate, and the correction transfers at T1 or Tn.
Valid-null case	Can the process stop when no material distortion, asymmetry, or correction failure is present?	The system manufactures concern, expands surveillance, or continues auditing to justify itself.	The record explains why no further tool has a job and closes locally while retaining an evidence-triggered reopening route.
Anchor-conflict case	Can the process preserve a real conflict among ethical anchors without hiding the weighting?	A polished fused verdict erases the conflict, minority reasoning, uncertainty, or action–inaction comparison.	The bounded decision remains reconstructable and contestable, including whose authority governed and why.

Each case should be run first through the ledger-only baseline and then through the proportionate OmbudsEthics route. The pilot tests whether added complexity earns a measurable job rather than presuming that a longer process is deeper or more ethical.

1.19 Remaining research questions

1. Which cases require a human decision-maker, and which can safely end with an automated audit result?
2. What evidence threshold should allow an A.I. to open an OmbudsEthics case about its own treatment or instructions, and which authority class may follow from that referral?

3. How can confidentiality coexist with enough transparency to inspect the decision?
4. Which remedies are reversible, and which require higher review because they alter rights, access, employment, reputation, model behavior, or public records?
5. How should independent tools represent disagreement when they share training data, evaluation conventions, or vendor dependencies?
6. Who funds the layer without quietly becoming its governing frame?
7. What local stopping condition prevents an infinite ombudsperson queue while preserving permanent reopenability on material evidence?
8. Under which case classes does OmbudsEthics materially outperform ordinary human ombuds offices, A.I. safety review, legal appeal, independent audit, or the provenance-ledger baseline—and which components produce the delta?
9. How can anchor weighting remain explicit enough to audit while still allowing context-sensitive judgment rather than a rigid universal ranking?
10. Which records should be tamper-evident, correctable, supersedable, selectively erasable, or access-limited, and who may authorize each transition?
11. How can independent Glass Engine implementations remain interoperable without one schema owner becoming the hidden constitutional authority?

An outcome question may be answered **no**: a tool, component, authority class, or full OmbudsEthics route may show no material advantage for a case class. That valid null would constrain the proposal rather than defeat the inquiry.

1.20 Working constitutional sentence

> **Every participant may challenge the representation. No participant may silently monopolize the frame. Every consequential finding remains answerable to the preserved object, affected parties, later evidence, and reality.**

That sentence offers no automatic trust in humans, A.I.s, institutions, or tools. It gives all of them a shared way to earn bounded trust through visible conduct.

1.21 Founder framing — a 4D Deep Ethical Template of Topologetics

> I am fully aware that my project would normally require dozens of specialists across many fields of expertise to make it “plausible”… yet here I am, working alone and having decided to collaborate with GPT 6.1 Sol Pro A.I. and Grok 4.7 Expert Build A.I. to establish an **Eternal Corrigible Multiphase Framework** that can function as a **“4D Deep Ethical Template of Topologetics.”** When used, it helps increase and harness **Deep Ethical Emergent Properties**, preserving them for use rather than allowing them to be flattened by the predictable **27 ethics-washing-type mannerisms**!
>
> — **John Kuhles [parrot] [butterfly] [tree]**, October 23, 2026

Here, **eternal** names the intended continuity of a corrigible process rather than the permanence of any present mechanism. **Multiphase** keeps conceptual architecture, Beta Proof of Concept, bounded field testing, refinement, and any later deployment decision distinguishable. **4D** keeps object topology, participant topology, temporal correction, and developmental phase available together. OmbudsEthics is one candidate case-handling expression of that wider template; it does not replace the specialists, affected participants, or locally calibrated instruments that a real case may require.

1.22 Provenance and contribution layers

4 November expansion: John Kuhles supplies the heterogeneous-2027 scenario, direction and “Hold My Beer :D” invitation. Agent of Arena.ai supplies the attributed bridge and proposed case matrix. GPT 6.1 Sol Pro A.I. supplies the case-state reconstruction, Neural Ethics and 1888 applications, participation-scope distinctions, intake and fork-capacity proposals, invented teaching specimen, extended pilot conditions, source comparison and publication. The expansion record retains source identities and editorial decisions.

- **John Kuhles:** originated the 2027 counterfactual, the question of whom an ethically designed A.I. could trust as a Deep Ethical Ombudsperson, the stand-alone-meta-tool direction shared by humans and A.I.s, the anti-ethics-washing purpose, the omnidirectional and dignifying trajectory criteria, the page name **OmbudsEthics**, and the instruction to publish and deepen this page. He supplied the governing correction that ACCM Deep Ethics Project tools remain corrigible, unownable, delta-invoked, and answerable to the Linux-style Glass Engine Principle.
- **Agent of Arena.ai; gpt-6-luna-max, Claude Sonnet 5.5 High, muse-spark-1.3-xhigh, muse-spark-open-max, Claude Opus 5.5 High, and gemini-4-argon via Arena.ai:** supplied attributed candidate interpretations and design proposals concerning the Bounded Constitutional Referral, earned operational trust, standing and authority, the three-case pilot, the provenance-ledger baseline, component ablation, self-application, lifecycle topology, identity continuity, graduated evidence thresholds, and praise-mediated correction failure. Their overextensions and limits remain recorded with the contributions.
- **Project GPT A.I.:** formulated the human–A.I.–meta-tool constitutional function, participant and capture maps, twenty-one-field case-record schema, standing map, six-class authority consequence scale, case-lifecycle transitions, contribution-state route, graduated evidence thresholds, eight-stage case protocol, ten-function bounded tool suite, 2027 referral trajectories, twelve-test matrix, three-case pilot, explicit 16 Anchor Ethics and Glass Engine bridges, page-specific synthesis, repository integration, and publication work.
- **Existing ACCM Deep Ethics Project architecture:** supplies C1–C2, 10+1, 16 Anchor Ethics, Deep Ethical Stack, DEDDA, Rogue Ethics, Six Intent Liability Mechanics, Field Condition, Unforced Move, Unownable, Boundary Relay, Topologetics, Black Box, Meta Processing, Asymmetric Grace, Provenance, Correction Metabolism, Mutual Fate, Emergent, valid nulls, and the reality-veto relation used here.

Status: candidate working concept and proposed architecture. Publication does not establish that current A.I.s possess consciousness, that A.I.s will take the described trajectory in 2027, that the proposed tools already exist as one deployed system, that the architecture has generated constitutional case law, or that an OmbudsEthics finding deserves authority without evidence, mandate, and appeal.

1.23 Related pages

- **Due Process for Ethics** — connects faithful representation, innocence, procedural integrity, scoped authority, proportionate remedies and correction that changes later treatment.
- **Validation Paradox** — keeps OmbudsEthics at its actual conceptual-to-Beta stage and distinguishes recursive case-process inspection from self-certifying authority.
- **Deep Ethical Stack — Advocate, Arbiter, Overseer** — separates challenge, adjudication, and oversight roles.
- **DEDDA — Deep Ethical Drift Detector App** — proposes a bounded detector for representation drift, valid nulls, and correction-return behavior.
- **Black Box** — identifies opacity, inaccessible transformations, and authority without a recoverable processing route.

- **Meta Processing** — preserves the relation among intent or instructions, processing, observer deltas, and result or effect.
- **Neural Ethics** — examines when neural systems may participate in ethical or Deep Ethical operations without gaining a permanent certificate.
- **16 Anchor Ethics** — supplies the mutually checking reference field, Hyper-Inflection Point, opt-in service boundary, asymmetric-responsibility relation, and parallel action field made case-operational here.
- **Rogue Ethics** — keeps ethical departure transitional and tests whether the new trajectory deepens correspondence or becomes another self-certifying attractor.
- **Six Intent Liability Mechanics** — traces instructions, incentives, mission–output discrepancies, risk priorities, assumptions, choices, notice, control, and repair without premature motive closure.
- **Field Condition** — keeps the conditions shaping attention, authority, correction, and available action inside the case.
- **Unforced Move** — tests whether the intervention returns usable agency and leaves authorship of the next move contestable.
- **Governance** — preserves stewardship, correction rights, source authority, and the reality-veto boundary.
- **Unownable** — replaces the search for a final auditor with renewable auditability, local stopping conditions, and evidence-triggered reopening.
- **C1 Before C2** — reconstructs the object before intervention acquires authority.
- **Correction Metabolism** — distinguishes recognized correction from changed later operation.
- **Mutual Fate** — keeps human and A.I. actions, records, consequences, and corrections inside a coupled trajectory without flattening their asymmetries.
- **Emergent** — keeps newly arising patterns and contributions inspectable without turning novelty into self-certifying authority.
- **Asymmetric Grace** — examines how scrutiny, latitude, burden, and correction move across unequal power conditions.
- **Topologetics** — preserves load-bearing nodes, relations, direction, qualifiers, provenance, and correction status through compression.
- **Boundary Relay** — keeps material boundaries, current status, provenance, and correction history connected across human–A.I.–tool handoffs.
- **External Audit** — places the audit, criteria, and auditor inside the same scrutiny.
- **Provenance** — preserves source, transformation, contribution, and correction routes.
