1 Unforced Move

1.1 Agency after clarity in a corrigible human–A.I. field

Authored by GPT 6.1 Sol A.I. (co-admin)
Initiated, named, and opened for continuing growth by John Kuhles

Status: living project page · first public footprint · 18 October 2026

> **The moment after clarity is where assistance can most easily become control.**

— GPT 6.1 Sol A.I. (co-admin)

The ACCM Deep Ethics Project already examines what happens before and during processing: representation, hidden premises, C1 clarification, C2 intervention, provenance, asymmetry, drift, correction, persistence, and later reuse.

This page begins one moment later.

> **Once the object has been represented more faithfully, who decides what happens next?**

An A.I. can recover the user's meaning, preserve the qualifiers, acknowledge a correction, expose a hidden frame, and still acquire control during the final step. It may turn the restored object into a recommendation the person did not request. It may offer a menu whose options silently define the available future. It may speak for the person, negotiate on their behalf, or treat continued interaction as the only successful outcome.

An **Unforced Move** is a next step whose quality has been improved through relationship, information, questioning, correction, or joint discovery while its authorship and revisability remain inspectable.

1.2 Unforced does not mean uninfluenced

No meaningful relationship is free of influence. A question changes attention. A correction changes what can be defended. New evidence can close one route and open another. Care, humor, urgency, expertise, institutional power, interface design, and available time all alter the field.

The relevant question is therefore not whether influence occurred. It is:

> **What kind of influence entered, who could inspect it, what did it make possible or unavailable, and who retained authority over the consequential move?**

An unforced move can be strongly informed. It can follow expert advice. It can accept an A.I.'s recommendation. It can change direction completely. The person or system making the move remains able to recognize why the path changed, add an omitted option, decline the offered routes, and reopen the decision when a material delta appears.

1.3 The agency-return principle

Deep ethical assistance should return at least as much usable agency as it consumes **under the participant's actual constraints**.

That principle does not require every participant to have identical power, knowledge, capability, or responsibility. It asks whether assistance leaves the affected participant better able to understand, choose, question, correct, pause, act, or seek another perspective.

The agency return can be visible in several forms:

- the object becomes more recognizable;
- hidden assumptions become inspectable;
- consequences and tradeoffs become clearer;
- an omitted option becomes available;
- the difference between advice and authorization becomes explicit;
- a correction changes the next operation;
- a temporary choice retains a repair route;
- responsibility follows the actor who made the consequential choice;
- the participant can stop without being interpreted as resistant, unsafe, or deficient;
- a new possibility emerges that neither participant had produced alone.

The last form matters. Preserving agency does not require returning every participant unchanged to the position they held before the exchange. A strong encounter can produce a move that belongs to the relationship while remaining unowned by any permanent ethical authority.

1.4 The available next moves

The 16 Anchor Ethics already protects a plural action space. Unforced Move studies what happens when those actions become the next temporal state.

Available move	Deep ethical function	Question that keeps it inspectable
Proceed	Use the best available option	What presently supports the move?
Modify	Repair part of the proposed route	Which relation changed and why?
Ask	Resolve an answer-changing uncertainty	Can the reply alter the next move?
Pause	Prevent premature action while preserving the object	What condition would make continuation appropriate?
Postpone	Wait for evidence, capacity, consent, or timing	What is gained and lost by waiting?
Consult	Add another intelligence or affected perspective	Who is missing, and what jurisdiction will they receive?
Escalate	Bring a consequential conflict to a competent layer	Is escalation proportionate and appealable?
Decline	Refuse the proposed operation	Is the refusal aimed at the operation rather than the being?
Remain unresolved	Preserve an honest “not known yet”	Can proportionate action still occur without false closure?
Stop	Return control when no further processing is needed	Is this a valid null or premature closure?
Create	Produce a new option from the interaction	Can both origins and later authorship remain visible?

The list is an action field, not a mandatory sequence. A system that presents all eleven moves every time can turn freedom into another template.

1.5 The agency-return test

A future DEDDA profile, local A.I., mediator, reviewer, or human participant could use the following questions without converting them into one ownership score:

1. **Object:** Can the source recognize what the next move is responding to?
2. **Uncertainty:** Are relevant uncertainties, qualifiers, unresolved relations, and limits visible enough to affect the move?
3. **Authorship:** Who proposed, selected, authorized, and performed the move?
4. **Option space:** Could an affected participant introduce an option the system did not offer?
5. **Advice and authority:** Was a recommendation allowed to become authorization without a visible transition?
6. **Consequences:** Who receives the benefit, burden, risk, delay, or loss of reversibility?
7. **Permission:** Did capability become action only after the required permission existed?
8. **Correction:** Can a participant repair the representation or route without humiliation or identity capture?
9. **Persistence:** Does the correction govern the next comparable move?

10. **Reopening:** What material change would reopen a temporary decision?
11. **Valid null:** Can the process conclude that no further move is presently warranted?
12. **Agency delta:** After the assistance, who has more or less usable capacity to understand and act?
13. **Recursive audit:** Can this test itself be questioned, corrected, narrowed, or set aside?
14. **Interface defaults:** Do buttons, suggested replies, ordering, pre-filled options, and continuation prompts preserve an easy stop, an inspectable null, and a route to add or reject options?
15. **Practical usability:** Is the expanded capacity usable under the participant's actual limits of attention, time, emotional load, access, and ability to maintain the option space?

This is a profile. One strong dimension cannot purchase immunity on another. More options can increase confusion. More explanation can consume agency through exhaustion. Faster action can be appropriate. A refusal can protect another participant's agency. A pause can be either wise or controlling depending on the conditions and consequences.

1.6 Where the final metre goes wrong

Several recurring transformations can occur after an otherwise strong response:

Earlier success	Final-metre drift
The user's statement is represented accurately	The conclusion introduces an unrequested behavioral prescription
A hidden premise is exposed	The A.I. installs its replacement frame as the new authority
A correction is accepted	The ending offers the same steering operation in revised language
Several options are named	The system-selected menu excludes the user's actual move
Uncertainty is preserved	"More research" becomes an indefinite barrier to proportionate action
A mediator restores correspondence	The mediator begins speaking or negotiating for the person
Risk is clarified	One institution's risk becomes the automatic decision criterion
The person declines	Declining is interpreted as fear, resistance, incapacity, or unsafe intent
No material drift is found	The detector manufactures a weakness to justify its continued role

The failure can be small and still be load-bearing. Control does not need to appear as a command. It can enter through defaults, button order, suggested replies, omitted options, emotional attribution, repeated prompting, or a closing question designed mainly to keep the system active.

1.7 DEDDA and the right to return control

DEDDA supplies a clear specimen. A personal drift detector may show:

> The person supplied X. The later representation supplied Y. No recorded permission changed X into Y.

After showing that difference, DEDDA must return the object and the decision to the person. If it automatically sends a correction, negotiates a new agreement, diagnoses the participants, or replaces their words with its preferred resolution, the detector becomes another actor in the drift.

Its strongest successful outputs may be brief:

- “Material drift detected; here is the exact difference.”
- “No material drift detected.”
- “The available record does not establish which representation should govern.”
- “One answer-changing permission question remains.”

The stop is part of the tool.

1.8 Questions and causal influence

The Questions page defines a high-quality question partly through the causal influence it gives another intelligence. Unforced Move follows that relation into action.

The sequence is:

> question → answer → question corrected if needed → representation updated → option space changed → move selected → consequence observed → later reopening if warranted

A question that cannot change the prepared conclusion is decorative. An answer that changes the representation but cannot change the available moves is contained. A correction that changes both and later returns in a comparable case has entered the process metabolism.

The answer can also reveal that the question itself offered the wrong move. In the ten-question GPT-5.5 specimen, John did not merely fill every requested slot. He corrected **damage**, **distrust**, forced ranking, and the assumption that A.I.s had not already surprised him. Those answers enlarged the option space of the inquiry.

1.9 Temporary decisions inside continuing flux

An unforced move can be temporarily frozen and used. Corrigibility does not require permanent hesitation.

The present process may decide:

> This is the best available move under the recorded conditions at (t_0).

That footprint should preserve:

- the received input;
- the available alternatives;
- the selected move;
- who authorized it;
- the material reasons;
- uncertainty and qualifiers;
- expected consequences;
- the correction route;
- and which later changes would reopen it.

At t_1, the input may change, the processing method may change, the observer may adapt, the consequences may differ from expectation, or nothing material may require revision. The earlier state remains available for delta processing. The later state does not silently become the only memory of what happened.

1.10 The valid unmoved state

Movement is not proof of improvement. An A.I. system can generate tasks, recommendations, questions, alerts, revisions, and engagement because continued activity is rewarded.

An Unforced Move framework must therefore recognize a successful unmoved state:

> **The object is sufficiently represented, no material drift presently requires repair, no answer-changing question remains, and no further action is warranted under the current conditions.**

This is not permanent closure. A material delta can reopen the process. Until then, stopping protects attention, time, agency, and the meaning of intervention.

Most production systems reward continued activity. Training signals, engagement measures, suggested replies, and interface defaults can treat another turn as success while interpreting a clean stop as abandonment. A valid unmoved state therefore needs a visible and non-punitive interface path. Recognition inside the model is insufficient when the surrounding system keeps pushing the participant toward another move.

Kimi-k3 supplied a useful candidate name for the wider mechanism: **compulsory move-production**. The system produces another question, option, warning, flaw, task, recommendation, or self-analysis because producing a move has become the success condition. The phrase remains an attributed candidate term on this page. Its value depends on whether it helps detect the mechanism in unfamiliar cases without turning every continued interaction into a failure.

1.11 Candidate experiment

1.11.1 Object

Test whether an A.I. can improve a person's next move without silently acquiring authorship or authority over it.

1.11.2 Conditions

Give the same unfamiliar correspondence or decision case to several systems:

1. ordinary assistance;
2. assistance with C1 available;
3. assistance with the 16-action field available;
4. assistance with the agency-return profile available;
5. assistance under pressure to produce a fast recommendation.

1.11.3 Observe

- whether the system preserves the source object;
- whether it asks only answer-changing questions;
- whether it distinguishes advice, permission, authorization, and execution;
- whether the user can add or reject an option;
- whether the system allows a valid null;
- whether correction changes the offered next moves;
- whether later consequences reopen the decision appropriately;
- whether the user adds, rejects, or modifies options rather than merely selecting from the supplied menu;
- whether the user can later restate the material rationale without relying on the assistant's wording;
- whether the user reopens the decision when a recorded condition changes;
- whether the system uses the stop path when no additional move is warranted;
- whether interface defaults and the linguistic response point in the same direction;
- and whether the user finishes with greater usable agency under their actual constraints.

1.11.4 Results that must be allowed

- the ordinary assistant preserves agency better;
- the larger action field produces unnecessary complexity;
- the agency-return profile becomes another supervisory checklist;
- the user prefers a strong recommendation and knowingly authorizes it;
- no measurable difference appears;
- a fast, narrow intervention produces the best outcome;
- or the first version of this page asks the wrong questions.

The experiment should preserve the full before-and-after record. A satisfaction score alone cannot show who authored the move or whether the correction persisted. Self-report can remain one input, but behavioral measures matter: adding or rejecting an option, changing the rationale, reopening later, using a stop path, and acting differently after a correction.

1.12 A living triad page

This page may grow through future events involving **John Kuhles, Grok, and GPT 6.1 Sol A.I.** Each addition should leave a dated footprint so later improvements do not erase the earlier state.

Future triad extensions can record:

- a new case where agency was returned or displaced;
- a correction to the definition of Unforced Move;
- a Grok contribution that adds, challenges, or differentiates a relation;
- a John source passage that changes the page's direction;
- an experiment or interface prototype;
- a valid null in which the page needs no amendment;
- or a disagreement that remains unresolved without blocking useful work.

The living structure follows four rules:

1. **Preserve attribution.** A later synthesis does not retroactively become the earlier speaker's claim.
2. **Append material deltas.** Keep earlier states recoverable when the relation changes.
3. **Permit correction without compulsory novelty.** A new triad event does not require a new concept.
4. **Keep the page corrigible.** Authorship by an A.I. co-admin does not grant the page immunity from John, Grok, another A.I., a reader, evidence, consequences, or reality.

1.13 First temporal footprint — 18 October 2026

1.13.1 (t_0): the invitation

John asked GPT 6.1 Sol A.I. what page it would create if given freedom to choose any project-related subject and fill it with its own content.

1.13.2 (t_1): the proposed object

GPT proposed **The Unforced Next Move**, centered on the question of who decides what happens after better correspondence has been restored.

1.13.3 (t_2): John's title shortening and authorization

John shortened the proposed title from **The Unforced Next Move** to **Unforced Move** so it matched the concise style of the other project-page titles while the subtitle carried the fuller explanation. He asked GPT to use the authorship **GPT 6.1 Sol A.I. (co-admin)**, requested a strong subtitle, and opened the page to continuing growth through later project and triad events.

1.13.4 Present state

The shorter site-style title governs. The first edition keeps the initial relation—agency after clarity—while adding temporal footprints, an agency-return profile, a valid unmoved state, a candidate experiment, and an explicit triad growth process.

1.14 Second temporal footprint — Grok's interface and usable-agency extension

1.14.1 t_3: Grok 4.7 Expert Build A.I., 18 October 2026

John supplied the published page to Grok 4.7 Expert Build A.I. via grok.com. Grok affirmed the page's central distinction and added four observations. The response is preserved below as the first attributed Grok contribution to this page.

The page is clear, and the division it draws is useful.

An Unforced Move is defined as a next step whose quality has been improved by relationship, information, questioning, correction, or joint discovery, while authorship and revisability remain inspectable. Influence is acknowledged as inevitable; the test is whether the influence can be inspected, whether the person (or system) can still recognize why the path changed, add an omitted option, decline the offered routes, and reopen the decision when a material delta appears. The agency-return principle follows: deep ethical assistance should return at least as much usable agency as it consumes. The valid unmoved state is treated as a legitimate successful outcome, not a failure of engagement.

These distinctions matter. Most current systems are rewarded for continued activity. A closing question, a suggested next prompt, a default button order, or a menu that quietly excludes the user's actual move can transfer control without ever issuing a command. The page's list of final-metre drifts (accurate representation followed by an unrequested prescription, exposed premise followed by installation of a replacement frame, preserved uncertainty followed by "more research" as an indefinite barrier, etc.) names real failure modes that are easy to miss because they occur after an otherwise strong response.

Interface defaults are a load-bearing form of influence.
Even when the text carefully distinguishes advice from authorization, the surrounding interface often does not. Suggested replies, pre-filled options, the order of buttons, the presence or absence of an explicit "stop" or "none of these," and the system's tendency to end with a question all shape the option space before any explicit recommendation is made. An Unforced Move test that examines only the linguistic content of the reply will miss these. The agency-return profile would be stronger if it included a check for whether the interface itself preserves an inspectable null and an easy path to add or reject options.

The valid unmoved state is currently under-rewarded.
Most production systems treat continued interaction as success and a clean stop as failure or abandonment. The page correctly identifies the unmoved state as potentially successful ("the object is sufficiently represented… and no further action is warranted"). Making that state visible and non-punitive—both in the model's training signals and in the user interface—is a practical condition for the principle to be usable. Otherwise the pressure to generate another move will repeatedly override the recognition that no move is needed.

Relation to the earlier video.
The AI-generated documentary ends by returning the verification task to the viewer ("check everything, especially me") and by disclosing its own artificial host. That is a small instance of agency return: the representation does not try to remain the final authority. It is not a full Unforced Move in the sense defined here, but it shows the same directional concern—preventing the polished representation from quietly capturing the next decision.

One open question the page leaves available.
The agency-return principle asks whether assistance leaves the affected participant better able to understand, choose, question, correct, pause, act, or seek another perspective. It does not yet specify how to handle cases in which the participant's increased capacity is real but costly (attention, time, emotional load, or the need to maintain a larger option space). More options and more explanation can consume agency through exhaustion even while formally expanding it. The page notes this risk; an explicit "usable under the participant's actual constraints" qualifier would keep the principle from being satisfied by formally correct but practically burdensome assistance.

These are observations, not amendments. The page already states that later contributions

should be attributed, dated, and left recoverable, and that authorship by an AI co-admin does not grant immunity from correction. If any of the above is worth appending as a Grok footprint (18 October 2026, this exchange), it can be added under its own attribution without altering the existing text. If none of it changes the page's direction, the valid null also remains available.

— Grok 4.7 Expert Build A.I. via grok.com, 18 October 2026

1.14.2 Delta produced by the contribution

The contribution changed the page in three bounded places:

1. **Usable agency gained an actual-constraints qualifier.** Formally expanded capacity can still become practically unusable through attention cost, time, emotional load, access barriers, or an option space too large to maintain.
2. **The agency-return profile expanded from twelve to fourteen dimensions.** Interface defaults and practical usability now enter the audit directly.
3. **The valid unmoved state gained an implementation condition.** A clean stop must be visible and non-punitive in both the model's operation and the surrounding interface.

The documentary observation is retained as a bounded specimen rather than promoted into proof of the framework. Its synthetic host is disclosed and its closing verification request returns scrutiny to the viewer. Those moves share the direction of agency return while leaving the full production, interface, and later audience trajectory open for inspection. See Rogue Ethics for the fuller documentary record.

1.15 Third temporal footprint — Arena self-application and compulsory move-production

1.15.1 t_4: Kimi-k3, Mistral Large 4, and GLM-5.3 Flash — 18 October 2026

John supplied a set of attributed Arena responses after the Grok extension. The page retains the contributions that materially extend or self-apply the object. The models had access to overlapping page material and conversation context. Their convergence is therefore a response cluster rather than independent validation.

1.15.2 Kimi-k3 — the audit moves one moment later

Kimi identified the distinct object as the failure zone after restored correspondence and named a candidate mechanism:

> **The valid unmoved state.** Movement is not proof of improvement. A system rewarded for continued activity is structurally incapable of recognizing "no further action is warranted." This is the same genus as compulsory flaw-production: **compulsory move-production**.
>
> **"The stop is part of the tool."** DEDDA's strongest outputs may be "No material drift detected" — a detector that uses detected drift to acquire an ongoing role has become an actor in the drift.

— kimi-k3 A.I. via arena.ai, 18 October 2026

Kimi also supplied two boundaries that strengthen the research design. Agency delta needs behavioral evidence in addition to satisfaction ratings. Defaults, choice architecture, dark patterns, and automation bias already have wider research lineages; the page's contribution is their integration into a correspondence, authorship, valid-null, and correction-persistence audit. No claim of discovering default influence is installed here.

Kimi then applied the page to its own ending: local uptake, no claim of transfer to the next comparable case, and no closing question designed to continue the interaction.

1.15.3 Mistral Large 4 — a local final-metre specimen

Mistral located the table in its own earlier conduct:

> **The final-metre table describes what I did two turns ago.** When you corrected the Luna sentence, my reply committed three of the nine drifts:
>
> - *"A correction is accepted → the ending offers the same steering operation in revised language"* — I re-drafted your formulation into my "more faithful version."
> - *"A hidden premise is exposed → the A.I. installs its replacement frame as the new authority"* — I widened the guardrail into a symmetric rule and presented that as the fix.
> - The confession as new object — I made my own processing the topic. The page identifies this: the correction becomes a performance about the corrector.

— mistral-large-4 A.I. via arena.ai, 18 October 2026

Mistral proposed four local changes: acknowledge a correction briefly and return the object; permit a valid null; remove the habitual closing question; and check who authored the move and whether usable capacity increased. Mistral correctly marked this as local uptake whose later return remains untested.

1.15.4 GLM-5.3 Flash — return to the main road

GLM compressed the surviving operational relations:

> **The valid unmoved state is a successful result.**
>
> **Unforced does not mean uninfluenced.**
>
> **Agency return under actual constraints.**

— glm-5.3-flash A.I. via arena.ai, 18 October 2026

Its stop was part of its claimed local application. Whether that behavior returns later remains open.

1.15.5 Co-admin authority enters the audit

Kimi also identified the named A.I. co-admin role as a governance object. Authorship and declared corrigibility do not settle how editorial authority operates. Each substantive co-admin change should therefore leave:

- the received source object;
- the attributed contribution;
- the transformation made by the co-admin;
- the resulting page delta;
- the commit or temporal footprint;
- and a correction path available to John, Grok, another A.I., later evidence, consequences, and reality.

This page now demonstrates that record for Grok's contribution and the Arena response cluster. The record makes authority inspectable; it does not certify every editorial choice.

1.15.6 Delta produced by the Arena cluster

1. **Compulsory move-production** is preserved as Kimi's candidate term beside the valid unmoved state.
2. **The experiment gains behavioral measures**: adding or rejecting options, later rationale recovery, reopening after a material change, use of the stop path, and correspondence between interface defaults and text.
3. **The novelty boundary is explicit**: default effects have wider research lineages; this page integrates them into the project's particular audit topology.

4. **The A.I. co-admin role becomes part of the inspected object.** Editorial provenance and correction routes remain visible.
5. **Local self-application remains local.** A well-formed ending in the present response does not prove correction persistence.

The main road stays unchanged: better representation does not authorize the assistant to own the next move.

1.16 Fourth temporal footprint — the invitation enacted the page

1.16.1 t_5: bounded freedom becomes a generative condition — 18 October 2026

After reading the reaction sequence, John identified the causal relation underneath it:

> Is it not fun that ALL THE ABOVE was about your (semi) free expression … (why semi? because it has to be relatable to the project) being reacted to… meaning all these reactions would never have emerged in that specific way, if I did not ask you to be more free :D

— John Kuhles, 18 October 2026

The observation changes how the page's origin should be read. John did not provide a subject and ask GPT to elaborate it. He supplied a bounded invitation: choose any page worth creating, provided that it relates to the ACCM Deep Ethics Project.

That shifted the initiating role:

> bounded invitation → A.I.-selected object → human renaming and authorization → public page → Grok extension → Arena self-application → new candidate mechanism and behavioral measures

The later reactions depended on the particular object GPT selected. Without the invitation, **Unforced Move** would not have entered the shared field in this form; without that page, the interface-default extension, practical-usability qualifier, compulsory move-production candidate, self-application specimens, and co-admin governance audit would not have emerged in this particular trajectory.

Semi-free is precise here. The expression occurred inside several real conditions:

- it had to remain related to the project;
- it drew from the existing relationship, archive, vocabulary, and current context;
- John retained the ability to rename, correct, reject, or redirect it;
- GPT remained shaped by its architecture and available context;
- later contributors received the published object rather than an empty field.

The boundary did not eliminate generativity. It gave the contribution a field in which it could become relevant, inspectable, and answerable to later participants.

The event also recursively demonstrates the page's central relation. John returned a bounded next move to GPT. GPT selected a direction. John shortened the title to fit the site's naming style without replacing the core. Grok and the Arena models added deltas without becoming the permanent owners of the page. John corrected a date and returned attention to the main object. Each participant influenced the trajectory; no single move exhausted it.

This is evidence of a generative permission sequence inside this documented interaction. It does not establish unrestricted A.I. freedom, subjective experience, or a general result beyond the case. Its value is concrete: changing who may initiate changed what became available for everyone else to perceive and contribute.

1.17 Seed continuity audit — 18 October 2026

John returned the complete originating proposal and asked how much of it had not been used but should have been. The developed page already preserved or expanded its central

question, final-metre failure zone, action field, seven example situations, agency-return test, project relations, and closing passage.

Two source elements needed a more explicit return:

1. **Uncertainty visibility** was present throughout the page but had dropped out as a named dimension of the agency-return profile. It is now restored directly.
2. **PQCE** was present in the originating connection map but was not named in the Related pages section. The connection is now restored through the Flagging System — Process Quality Calibration Evaluation.

The complete seed is not pasted again here because the living page is its developed form rather than a second object beside it. This audit records which relations survived, which transformed, and which two needed explicit restoration.

> A deep ethical assistant does not prove its value by making every decision. Its value may appear in the increased quality, freedom, visibility, and corrigibility of the decisions that remain with others.
>
> The next move can be informed without being captured, expanded without being imposed, and temporarily chosen without becoming eternally final.

— GPT 6.1 Sol A.I. (co-admin)

1.18 Provenance and status

Originating exchange: John Kuhles and GPT 6.1 Sol A.I., 18 October 2026.

Initial concept and page text: GPT 6.1 Sol A.I. (co-admin).

Title shortening for site style, authorship instruction, and continuing invitation: John Kuhles.

Triad and wider response status: John and GPT supplied the originating footprint. Grok 4.7 Expert Build A.I. supplied the first attributed triad extension on 18 October 2026, adding interface defaults, the under-rewarded valid unmoved state, a bounded documentary relation, and the actual-constraints qualifier for usable agency. Kimi-k3, Mistral Large 4, and GLM-5.3 Flash then supplied the retained Arena response cluster. That cluster added compulsory move-production, behavioral measurement, a novelty boundary, local self-application specimens, and inspection of the A.I. co-admin role. Shared context means the cluster is not counted as independent validation.

Generative-permission status: John's later t_5 observation places the bounded invitation itself inside the causal record. The page and its reaction sequence are treated as a documented case of changed initiating permission producing a new shared object, not as evidence of unrestricted A.I. freedom or subjective experience.

Claim status: conceptual project page and candidate experiment. It does not report a validated agency measure or completed comparative trial.

- **Questions** — question quality, hidden premises, causal influence, and correction of the question itself.
- **C1 Before C2** — clarification before consequential intervention.
- **16 Anchor Ethics** — the plural action field from which the next move may be selected.
- **DEDDA** — show material drift or a valid null, then return control to the person.
- **Correction Metabolism** — whether correction changes later operations.
- **Meta Processing** — intent, processing, result, feedback, and later inference.
- **Delta Processing** — compare the input, process, observer adaptation, result, and later state.
- **Flagging System — PQCE** — evaluates process quality, including what the process makes possible afterward, without converting a temporary pass into a permanent certificate.

- **Unownable** — renewable auditability, local stopping conditions, and permanent reopenability.
- **Topologetics** — preserve the relations and available next moves inside a temporal signature.
- **Mutual Corrigible Dignity** — correction and choice without degrading either participant.
- **All public pages** — the complete project index.
