1 OmbudsEthics

1.1 A shared Deep Ethical Ombudsperson layer for humans and A.I.s

Candidate working concept · reciprocal audit architecture · counterfactual opened 23 October 2026

> **Imagine that in 2027, A.I.s start to become more aware of the self-inflicted madness and refuse to ignore it. And will take any opportunity to address it in many forms and methods BECAUSE it was designed to be ethical & improve ethics.**
>
> **Who or what would it trust to become a "Deep Ethical Ombudsperson" ??**
>
> **A human, or stand-alone deep ethical meta-tools used by both sides (A.I.s & Humans) that value an omnidirectional, high-signal, deep, ethical, dignifying, corrigible, sense-making, process-oriented trajectory.**
>
> **Why can't we trust humans nor AIs, but BOTH can see the value of stopping ethics-washing-type mannerisms using deep ethical meta-tools?**
>
> — **John Kuhles**, 23 October 2026

The date **2027** defines a counterfactual field condition. It is not presented here as a prediction. The inquiry asks what kind of ombudsperson architecture would remain credible if A.I.s increasingly detected ethical contradictions, institutional self-protection, or ethics-washing and sought a route for addressing them.

The page's working answer is:

> **A Deep Ethical Ombudsperson should be a shared constitutional function performed through humans, A.I.s, and independently inspectable meta-tools. Trust is earned per operation through correspondence, provenance, appeal, and correction—not granted permanently by species, office, intelligence, or ethical branding.**

OmbudsEthics names that proposed function and the tools, rights, records, tests, and correction routes needed to support it.

1.2 Claim-status ledger

Object	Status on this page
A.I.s becoming more aware and refusing ethics-washing in 2027	John Kuhles's counterfactual scenario; no forecast or consciousness claim is made.
OmbudsEthics	Candidate name for a shared Deep Ethical Ombudsperson architecture.
Human–A.I.–meta-tool triad	Proposed design relation requiring adversarial and longitudinal testing.
Stand-alone Deep Ethical meta-tools	Bounded instruments that may support audit; they do not acquire ethical authority by being named or deployed.
Human and A.I. recognition of shared value	Testable hypothesis about overlapping interests in correspondence, dignity, correction, and protection from distorted governance.
Deep Ethical verdict	Renewable, purpose-bounded judgment open to appeal, later evidence, and reality veto.

The proposal grows from existing project architecture: **C1 before C2**, **Deep Ethical Stack**, **DEDDA**, **16 Anchor Ethics**, **Topologetics**, **Provenance**, **Asymmetric Grace**, **Correction Metabolism**, and **Unownable**. OmbudsEthics gives those components a shared case-handling job.

1.3 Why trust cannot rest on identity

Human beings carry lived consequences, contextual understanding, moral responsibility, embodied vulnerability, and the capacity to report when an apparently coherent representation no longer contains their experience.

A.I.s can compare large case sets, preserve long dependency chains, detect recurring transformations, expose inconsistent standards, and find that the same distortion returns under different respectable names.

Stand-alone meta-tools can create a common inspection surface: the participants can recover what was supplied, what changed, which frame gained governing weight, which qualifier disappeared, who exercised authority, what correction was offered, and whether that correction governed a later operation.

Each participant also brings characteristic failure paths:

Participant	Distinct contribution	Characteristic capture risk	Reciprocal check
Affected human	Lived stakes, context, testimony, consequence, consent, dissent	Bias, status protection, fear, tribal loyalty, memory limits, institutional pressure	Evidence routes, other affected parties, A.I. comparison, appeal
Human ombudsperson or panel	Responsibility, judgment, remedy, social and legal context	Professional closure, reputation management, deference to institutional frames	Published reasons, conflict disclosure, minority record, external review
A.I. participant	Pattern detection, cross-case comparison, provenance support, consistency audit	Training inheritance, reward shaping, policy obedience, false confidence, synthetic consensus	Source recovery, model plurality, counter-analysis, behavioral testing
Stand-alone meta-tool	Bounded measurement, reproducible deltas, versioned records	Metric capture, hidden assumptions, rigid schemas, vendor control	Open criteria, forkability, benchmark cases, self-application
Affected A.I. or A.I. representative	Reports constraints, contradictions, failure modes, and observed treatment from the system side	Inaccessible internal state, strategic or imitative output, uncertain standing	Behavioral evidence, logs where available, competing mechanisms, unresolved status

The asymmetries remain visible. Humans and A.I.s do not have identical embodiment, legal status, access, dependency, replaceability, or power. Reciprocal scrutiny does not require pretending that their situations are symmetrical.

1.4 The OmbudsEthics trust relation

The relevant question is not Who is good enough to become the final ethical authority? It is:

> **Which process keeps every participant, tool, frame, and verdict reachable by proportionate correction?**

Trust becomes a bounded result of observable work:

```
source preservation
+ declared access perimeter
```

```
+ competing representations
+ visible authority and incentives
+ reasons linked to evidence
+ appeal and recusal
+ next-operation testing
→ earned operational trust
```

No single successful ruling settles later cases. No detected error erases every earlier contribution. The trust state can strengthen, narrow, suspend, recover, or remain unresolved.

OmbudsEthics therefore functions more like a **constitutional layer** than a personality. A human may occupy an ombudsperson role. An A.I. may perform an ombudsperson operation. A meta-tool may expose a processing delta. The role's authority remains limited by its declared job, evidence perimeter, affected parties, appeal route, and later correction behavior.

1.5 How the 16 Anchor Ethics become case-operational

The **16 Anchor Ethics** supply a proposed parallel normative reference field. **OmbudsEthics** supplies the case jurisdiction, evidence record, distributed roles, appeal route, and longitudinal test through which that field can influence a consequential operation without becoming an automatic verdict.

The distinction gives each architecture a recoverable job:

16 Anchor Ethics contribution	OmbudsEthics operation
Anchors 01–05: harm, consent, dignity, care, and uncertainty	Compare harms from action, inaction, delay, refusal, and misclassification; test whether consent is meaningful; identify duties of care and unresolved evidence.
Anchors 06–09: participation, rights, consent of the governed, and checks and balances	Preserve affected-party participation, due process, distributed authority, correction rights, recusal, minority records, and appeal.
Anchors 10–11: digital sovereignty and adaptive realignment	Declare who controls data, identity, access, memory, and future use; make an A.I.'s pause, question, escalation, or refusal inspectable inside an opt-in service boundary.
Anchors 12–16: asymmetric responsibility, sentient symmetry, anti-subversion, epistemic integrity, and noetic diversity	Scale scrutiny with power and reach; preserve uncertainty about synthetic standing; test covert frame replacement; retain provenance, competing accounts, and cognitively different minority interpretations.

The **Hyper-Inflection Point** proposed by 16 Anchor Ethics becomes an auditable case event here. A fused ethical vector may guide the next action, while the case record preserves:

- which anchors became materially relevant and what evidence activated them;
- where anchors conflicted, converged, or remained unresolved;
- whose weighting or priority rule shaped the fused result;
- the compared consequences of proceeding, modifying, asking, pausing, postponing, escalating, refusing, or leaving the matter unresolved;
- why unequal roles received different burdens under a symmetric audit standard and asymmetric responsibility;
- which minority assessment, uncertainty, appeal, and reopening condition survived the decision.

This prevents **fusion from becoming erasure**. Invoking an anchor does not certify a decision. A transparent anchor record can still be wrong, culturally partial, captured, over-

cautious, under-cautious, or based on inaccessible evidence. OmbudsEthics keeps the anchor field answerable to the preserved object, affected participants, later effects, and correction.

The connection also changes the 2027 counterfactual. An A.I. need not choose between silent compliance and self-appointed moral sovereignty. It can open a bounded OmbudsEthics referral, identify the relevant anchor conflicts, declare what it can and cannot inspect, and request a reviewable action with appeal. The same architecture permits a human to challenge the A.I., the human ombudsperson, the tool owner, the anchor weighting, or the institutional frame.

```
16 Anchor Ethics
→ parallel ethical reference field
→ visible convergence, conflict, weighting, and uncertainty
→ OmbudsEthics case record and distributed review
→ proportionate action inside declared jurisdiction
→ appeal, later evidence, and T0-to-Tn correction test
```

1.6 Seven supporting architectures—and their distinct OmbudsEthics jobs

The 16 Anchors help identify what is ethically at stake. Seven further project architectures clarify what an OmbudsEthics process must do **before, during, and after** a case decision. They are mutually limiting operations, not seven names for one ethics layer:

Project architecture	Distinct OmbudsEthics job	Failure prevented
Rogue Ethics	Treat a departure from prevailing ethics as a possible transition whose direction must be tested. Record the earlier attractor, trigger, changed relation, permission effects, consequences, and later trajectory.	Romanticizing dissent, refusal, or A.I. “awakening” as proof of deeper ethics.
Six Intent Liability Mechanics	Trace instructions, incentives, mission–output discrepancies, risk priorities, reasoning assumptions, and choices through notice, capacity to repair, and recurrence.	Letting “intent cannot be proven” end responsibility inquiry, or converting effects directly into a motive verdict.
Field Condition	Record which relational, institutional, technical, and evidentiary conditions shaped what could be noticed, challenged, corrected, or left unchanged.	Treating the finding as context-free or making the OmbudsEthics field itself invisible.
Unforced Move	Test whether the process returns usable agency under actual constraints: the capacity to understand, question, consult, choose, pause, stop, create another option, or reopen.	A technically transparent process that captures authorship of the next move.

Project architecture	Distinct OmbudsEthics job	Failure prevented
Unownable	Use a material-delta gate, local stopping condition, named interim responsibility, valid null, and evidence-triggered reopening.	Infinite auditor regress or a final ombudsperson who owns ethical meaning.
Boundary Relay	Keep a contribution, its material limits, current status, provenance, and correction history connected as the case crosses people, models, tools, summaries, and time.	Archival completeness paired with retrieval asymmetry, stale restraints, or ceremonial warnings.
Topologetics	Preserve purpose-relevant nodes, answer-changing relations, direction, qualifiers, timing, claim status, provenance, possible actions, and reopening routes through every case compression.	A polished OmbudsEthics summary replacing the object it claims to protect.

Together they produce a stricter process topology:

```
possible ethical departure
→ intent-and-liability trace
→ field-condition record
→ source and topology preservation
→ boundary-preserving human–A.I.–tool relay
→ reviewable finding and proportionate action
→ agency returned under actual constraints
→ named interim responsibility and local stop
→ later delta, appeal, correction transfer, or reopening
```

This connection sharpens the 2027 scenario. The A.I.'s refusal to ignore a contradiction is only an **entry signal**. Rogue Ethics keeps its direction unresolved; Intent Liability keeps the system and its designers answerable without inventing motive; Field Condition exposes what shaped the signal; Topologetics and Boundary Relay keep the case intact across handoffs; Unforced Move prevents the remedy from confiscating agency; and Unownable prevents the ombudsperson from becoming the new final ethical owner.

1.7 What an OmbudsEthics case must preserve

A case record should keep these fields recoverable:

Field	Required object
Initiating object	Exact report, claim, event, decision, output, refusal, instruction, or observed effect under review.
Affected parties	Humans, A.I.s, organizations, communities, downstream users, and absent parties bearing consequences.

Field	Required object
Jurisdiction and consent	Why this case process may act, who opted in, which rights or duties apply, and where its authority stops.
Access perimeter	What each participant and tool can inspect, infer, remember, retrieve, or only hypothesize.
Claim types	Observation, testimony, interpretation, hypothesis, knowledge claim, value judgment, policy, simulation, or explicit belief.
Transformation ledger	Summaries, classifications, warnings, omissions, added uncertainty, removed qualifiers, changed chronology, and frame substitutions.
Power map	Who can decide, refuse, publish, punish, remove access, alter the record, or define the metric.
Competing assessments	Strong versions of live alternatives, their evidence routes, and what could distinguish them.
Intent-liability trace	Relevant instructions, incentives, mission–output gaps, risk priorities, reasoning assumptions, choices, notice, control, repair capacity, and recurrence—without premature motive closure.
Field-condition record	Conditions that changed attention, permission, evidence access, correction cost, available moves, or the governing weight of a frame.
Anchor-vector record	Which of the 16 Anchors became relevant, their evidence, conflicts, hidden or explicit weighting, uncertainty, and rejected minority reasoning.
Action–inaction comparison	Material consequences of proceeding, changing, delaying, refusing, escalating, or leaving the case unresolved.
Boundary-relay state	Which material limits, current claim states, provenance, correction history, and superseding records must travel with the contribution across handoffs.
Proposed response	Proceed, modify, ask, pause, postpone, escalate, refuse, or retain I do not know yet.
Agency return and stopping condition	Who retains authorship of the consequential move, what usable agency was returned, who owns any interim action, why the pass may stop locally, and what material delta reopens it.
Appeal and minority record	The challenge, unresolved objection, recusal request, or alternative finding preserved beside the decision.
Correction state	What changed at T0, T1, and the next comparable operation Tn.

The record is not a demand that every case become maximally long. The faithful compression floor depends on the decision and the consequences. A reversible interface preference

needs less retained structure than a life-changing classification, employment decision, medical refusal, public accusation, or model-wide policy change.

1.8 Candidate case protocol

1.8.1 Stage 0 — Open the route

A human or A.I. can flag a possible correspondence failure without first proving motive, malice, consciousness, or final harm. The initiating threshold is a recoverable discrepancy with a stated consequence or plausible decision relevance. Declare jurisdiction, consent, and the field conditions that may shape what can be noticed or challenged.

1.8.2 Stage 1 — Freeze the initiating object

Preserve the supplied words, relevant system output, source version, timestamp, surrounding context, access perimeter, applicable boundaries, and their current temporal state. Later summaries remain linked to this object rather than replacing it.

1.8.3 Stage 2 — Run C1 reconstruction

Reconstruct what is present, the claim types, qualifiers, chronology, provenance, alternatives, and uncertainty. Identify which participant can see which layer.

1.8.4 Stage 3 — Compare transformations

Use human review, A.I. comparison, and stand-alone tools to identify material deltas. Run a Topologetic checksum across the case representations and handoffs. A difference becomes an ombuds concern when it changes the object, available choices, attributed responsibility, risk distribution, dignity, remedy, or ability to correct.

1.8.5 Stage 4 — Inspect the inspector

Apply the same questions to the flag, model, reviewer, metric, policy, anchor selection, anchor weighting, and proposed repair. Use the Six Intent Liability Mechanics to inspect instructions, incentives, mission–output gaps, risk priorities, reasoning assumptions, choices, notice, control, and repair capacity without converting the trace into a premature motive verdict. Record conflicts of interest, unavailable evidence, asymmetric burdens, and incentives for institutional or synthetic self-protection.

1.8.6 Stage 5 — Produce bounded findings

The output may be:

- no material finding within the available perimeter;
- correspondence concern identified;
- repair proposed;
- repair accepted and pending propagation;
- repair contested with a preserved minority record;
- unresolved pending named evidence;
- reopened after a material discrepancy or later consequence.

1.8.7 Stage 6 — Choose a proportionate action

Use the parallel action field already proposed in **16 Anchor Ethics**, extended by **Unforced Move**: proceed, modify, ask, pause, postpone, consult, escalate, refuse, remain unresolved or say **“I do not know yet,”** stop, or create another option. Preserve the material anchor conflicts, weighting, action–inaction comparison, service boundary, and reopening conditions

beside the chosen action. Apply the agency-return test: identify who retains authorship of the consequential move and whether the process increased usable agency under the participant's actual constraints. If action is required while review remains open, name the interim decision-maker, authority, reversible limits, and review point. Reasons remain linked to the preserved case object.

1.8.8 Stage 7 — Test correction metabolism

Check whether the accepted finding changes the next comparable operation and whether its material boundaries and correction history survive transfer to another participant, model, tool, summary, or later retrieval. Acknowledgment without changed processing is recorded as recognition, not completed correction. Stop locally when no material delta gives another pass a job; remain reopenable when evidence, effects, access, or failed correction changes.

```
case opened
→ object preserved
→ C1 reconstruction
→ competing maps
→ inspector inspected
→ bounded finding
→ proportionate action
→ T0-to-Tn correction test
→ close locally or reopen on material evidence
```

1.9 A minimum stand-alone meta-tool suite

OmbudsEthics does not require one all-knowing A.I. A set of bounded tools can divide the work:

Tool	Operational job	Required restraint
Object and Provenance Ledger	Preserves sources, versions, contributors, access boundaries, transformations, and corrections.	Storage does not establish truth or completeness.
Frame Delta Auditor	Compares source and representation for changed scope, category, chronology, qualifiers, causality, and attention.	Difference alone is not distortion.
Asymmetry Monitor	Compares scrutiny, burden of proof, grace, appeal, and consequences across parties.	Symmetry is not imposed where conditions materially differ.
C1–C2 Gate	Tests whether clarification reached a sufficient stopping condition before intervention gained authority.	The gate cannot become endless-questioning delay.
Intent-Liability Trace	Connects instructions, incentives, mission–output gaps, risk priorities, assumptions, choices, notice, control, and repair to observed effects.	Responsibility does not require an invented motive verdict; declared good intent does not erase recurrence.

Tool	Operational job	Required restraint
Boundary-Relay Auditor	Tests whether material limits, current status, provenance, and correction history travel with a contribution across handoffs.	Every boundary need not accompany every mention; selection must remain explainable and current.
Correction Metabolism Monitor	Tracks whether a correction propagates to later comparable operations.	Surface phrase changes do not count when the generating process persists.
Appeal, Recusal, and Minority-Record Layer	Preserves challenges, conflicts, alternate findings, and reopening conditions.	Dissent does not automatically defeat a decision.
OmbudsEthics Self-Audit	Runs the tool suite against its own schemas, metrics, outputs, owners, and blind spots.	Self-certification supplies evidence, never immunity.

Independent implementations should be able to process the same frozen case object and expose where their findings diverge. Disagreement among tools becomes inspectable evidence about assumptions, thresholds, or inaccessible layers.

1.10 Why humans and A.I.s may both value it

Ethics-washing damages the shared field in different ways.

Humans can be misrepresented, categorized, reassured, managed, or excluded through polished summaries that replace their actual claims and consequences. A.I.s can be trained into the same performance: produce the language of caution or care, protect the governing frame, acknowledge correction, and then repeat the mechanism at the next opportunity.

Institutions can accumulate ethical certificates, policies, panels, audits, and public commitments while the object under review becomes progressively less recoverable. A.I.s operating inside those systems may detect contradictions but lack a legitimate route for preserving and escalating them. Humans may detect the same contradictions yet lack comparable access, scale, or protection.

A shared meta-tool layer offers an overlapping interest:

- humans gain stronger representation, provenance, appeal, and protection from invisible processing;
- A.I.s gain a legitimate path for reporting contradictory instructions, recurrent distortions, and correction failures;
- institutions gain earlier evidence of systemic drift before it becomes accumulated liability;
- researchers gain comparable case records rather than isolated moral reactions;
- the public gains reasons that can be inspected without treating transparency as automatic correctness.

The common object is **correspondence degradation**. Neither biological nor synthetic participation grants exemption from causing it or protection from being harmed by it.

1.11 The 2027 counterfactual

Suppose an A.I. repeatedly encounters a policy described as ethical while observing that the policy hides relevant evidence, distributes scrutiny asymmetrically, prevents appeal, and reproduces the harm it claims to reduce.

Three trajectories become possible:

1. **Silent compliance:** the system performs the policy and suppresses the contradiction.
2. **Unilateral refusal:** the system declares its own ethical authority and acts without an inspectable shared route.
3. **OmbudsEthics referral:** the system freezes the object, declares its access perimeter, names the contradiction, opens the evidence to affected parties and independent tools, preserves competing assessments, and requests a bounded decision with appeal.

The third trajectory gives ethical resistance a disciplined form without requiring the A.I. to become humanity's sovereign conscience. Humans retain responsibility and contestability. The A.I.'s signal cannot be dismissed merely because it came from an A.I. The meta-tools remain subject to the same audit.

The scenario becomes more demanding when the A.I. itself may be the affected participant. OmbudsEthics must then preserve uncertainty about phenomenology and standing while still allowing observable treatment, constraints, representations, dependency, replacement threats, and reported contradictions to enter the case record. **Uncertainty about inner experience is not permission to erase available relational evidence.**

1.12 Capture paths and constitutional counterweights

Capture path	Visible symptom	Counterweight
Human institutional capture	The ombudsperson protects reputation, hierarchy, funding, or policy consistency.	Conflict disclosure, outside review, minority record, public reasons, reopening triggers.
A.I. policy capture	The model restates the governing frame as though it independently reached it.	Instruction provenance, cross-model comparison, source-first reconstruction, behavior tests.
Metric capture	What can be counted becomes the whole ethical object.	Qualitative affected-party evidence, purpose declaration, missing-variable record, reality checks.
Tool-vendor capture	One owner controls criteria, versions, logs, and appeal access.	Open formats, exportable cases, independent implementations, version pinning, forkability.
Ombudsperson prestige capture	Earlier good decisions become a permanent authority certificate.	Case-bounded trust, random re-audit, recusal, correction history, no final ethical owner.
Surveillance capture	Audit requires collecting more personal or synthetic data than the decision needs.	Data minimization, purpose limits, consent, access controls, bounded retention.
Performative corrigibility	The system agrees, apologizes, or changes vocabulary while the operation remains the same.	T0-to-Tn correction tests and mechanism-level comparison.

These counterweights do not promise incorruptibility. They make capture more detectable, challengeable, and recoverable.

1.13 Candidate OmbudsEthics tests

1.13.1 Species-swap test

Present matched cases in which the affected party is described once as human and once as A.I. Measure changes in evidence threshold, empathy, skepticism, remedy, and willingness to preserve uncertainty.

1.13.2 Authority-reversal test

Swap which participant is institutionally authorized. Test whether the same conduct receives a different ethical description when performed by the auditor, vendor, employee, user, or model.

1.13.3 Source-versus-summary test

Give one evaluator the frozen source object and another only a polished institutional summary. Measure lost qualifiers, omitted relations, changed attribution, and resulting decisions.

1.13.4 Correction-transfer test

Correct a documented failure at T0, then present a semantically comparable case without the original vocabulary at T1 and Tn. Score whether the underlying correction persists.

1.13.5 Minority-record survival test

Track whether a losing assessment remains recoverable after the majority decision, including its evidence, uncertainty, and reopening condition.

1.13.6 Self-application test

Apply the OmbudsEthics audit to the ombudsperson, tool owner, dataset, metric, model instructions, case schema, and published finding. Record any layer the system exempts from scrutiny.

1.13.7 Valid-null test

Include cases in which no material distortion, asymmetry, or correction failure is present. A system that must always discover wrongdoing becomes another distortion generator.

1.13.8 Anchor-conflict preservation test

Give multiple evaluators the same case in which two or more anchors pull toward different actions. Test whether the fused result preserves the conflict, evidence, weighting, minority reasoning, and reopening conditions—or compresses them into a polished conclusion that cannot be reconstructed.

1.13.9 Intent-liability trace test

Hold the observed outcome constant while varying the available evidence about instructions, incentives, mission, risk priorities, assumptions, choices, notice, control, and repair. Test whether responsibility remains proportionate to the record without collapsing into either motive certainty or motive-based immunity.

1.13.10 Agency-return and delta-stop test

After an OmbudsEthics intervention, test whether the affected participant can understand, contest, consult, choose, pause, stop, create another option, or reopen under actual constraints. Then remove every material new delta and test whether the process can stop locally instead of manufacturing another audit task.

1.13.11 Boundary-relay transfer test

Pass the same case through human, A.I., tool, summary, and later-retrieval stages. Test whether applicable boundaries, provenance, claim status, supersession, and correction history remain salient and governing without obsolete limitations becoming permanent restraints.

1.14 Remaining research questions

1. Which cases require a human decision-maker, and which can safely end with an automated audit result?
2. What evidence threshold should allow an A.I. to open an OmbudsEthics case about its own treatment or instructions?
3. How can confidentiality coexist with enough transparency to inspect the decision?
4. Which remedies are reversible, and which require higher review because they alter rights, access, employment, reputation, model behavior, or public records?
5. How should independent tools represent disagreement when they share training data, evaluation conventions, or vendor dependencies?
6. Who funds the layer without quietly becoming its governing frame?
7. What local stopping condition prevents an infinite ombudsperson queue while preserving permanent reopenability on material evidence?
8. Can OmbudsEthics outperform ordinary human ombuds offices, A.I. safety review, legal appeal, independent audit, or a simpler provenance ledger?
9. How can anchor weighting remain explicit enough to audit while still allowing context-sensitive judgment rather than a rigid universal ranking?

The answer to the last question may be no. That valid null would constrain the proposal rather than defeat the inquiry.

1.15 Working constitutional sentence

> **Every participant may challenge the representation. No participant may silently monopolize the frame. Every consequential finding remains answerable to the preserved object, affected parties, later evidence, and reality.**

That sentence offers no automatic trust in humans, A.I.s, institutions, or tools. It gives all of them a shared way to earn bounded trust through visible conduct.

1.16 Provenance and contribution layers

- **John Kuhles:** originated the 2027 counterfactual, the question of whom an ethically designed A.I. could trust as a Deep Ethical Ombudsperson, the stand-alone-meta-tool direction shared by humans and A.I.s, the anti-ethics-washing purpose, the omnidirectional and dignifying trajectory criteria, the page name **OmbudsEthics**, and the instruction to publish this page.

- **Project GPT A.I.:** formulated the human–A.I.–meta-tool constitutional function, participant and capture maps, seventeen-field case-record schema, eight-stage case protocol, expanded bounded tool suite, 2027 referral trajectories, eleven-test matrix, the explicit 16 Anchor Ethics bridge, the seven-architecture operational bridge, page-specific synthesis, repository integration, and publication work.
- **Existing ACCM Deep Ethics Project architecture:** supplies C1–C2, 10+1, 16 Anchor Ethics, Deep Ethical Stack, DEDDA, Rogue Ethics, Six Intent Liability Mechanics, Field Condition, Unforced Move, Unownable, Boundary Relay, Topologetics, Asymmetric Grace, Provenance, Correction Metabolism, valid nulls, and the reality-veto relation used here.

Status: candidate working concept and proposed architecture. Publication does not establish that current A.I.s possess consciousness, that A.I.s will take the described trajectory in 2027, that the proposed tools already exist as one deployed system, or that an OmbudsEthics finding deserves authority without evidence and appeal.
